Abstract

The variational implicit-solvent model (VISM) is an efficient approach to biomolecular interactions, where electrostatic interactions are crucial. The total VISM free energy of a dielectric boundary (i.e., solute-solvent interface) consists of the interfacial energy, solute-solvent interaction energy, and dielectric electrostatic energy. The last part is the maximum value of the classical and concave Poisson–Boltzmann (PB) energy functional of electrostatic potentials, with the maximizer being the equilibrium electrostatic potential governed by the PB equation. For the consistency of energy minimization and computational stability, here we propose alternatively to minimize the convex Legendre-transformed Poisson–Boltzmann (LTPB) electrostatic energy functional of all dielectric displacements constrained by Gauss’ law in the solute region. Both integrable and discrete solute charge densities are treated, and the duality of the LTPB and PB functionals is established. A penalty method is designed for the constrained minimization of the LTPB functional. In application to biomolecular interactions, we minimize the total VISM free energy iteratively, while in each step of such iteration, minimize the LTPB energy. Convergence of such a min-min algorithm is shown. Our numerical results on the solvation of a single ion indicate that the LTPB performs better than the PB formulation, providing possibilities for efficient biomolecular simulations.

Key words and phrases: Variational implicit-solvent model, Poisson–Boltzmann theory, Legendre transform, dielectric boundary force, penalty method, a min-min optimization algorithm.

1 Introduction

In a variational implicit-solvent model (VISM) [10, 11, 35, 40] (cf. also related models [2, 26, 31]), one minimizes a solvation free-energy functional of all possible solute-solvent interfaces (i.e., dielectric boundaries) to determine an equilibrium system of charged molecules (such as proteins) immersed in an aqueous solvent (i.e., water or salted water) and estimate the solvation free
energy. The VISM free energy consists of the solute-solvent interfacial energy, the solute-solvent interaction energy, and the electrostatic energy. The last part is often described through the equilibrium electrostatic potential \( \phi_T : \Omega \to \mathbb{R} \) which is governed by the dielectric boundary Poisson–Boltzmann (PB) equation (PBE) \([1, 6, 9, 14, 34, 40]\)

\[
\nabla \cdot \varepsilon R \nabla \phi_T - \chi_+ B' (\phi_T) = -f \quad \text{in} \ \Omega, \tag{1.1}
\]

together with some boundary conditions. Here, \( \Omega \subset \mathbb{R}^3 \) is the underlying solvation region, \( \Gamma \) is the dielectric boundary that divides \( \Omega \) into the solute region \( \Omega_- \) and the solvent region \( \Omega_+ \), \( \chi_+ = \chi_{\Omega_+} \) is the characteristic function of \( \Omega_+ \), and \( \varepsilon R : \Omega \to \mathbb{R} \) is the dielectric coefficient defined by

\[
\varepsilon R (x) = \begin{cases} 
\varepsilon_- & \text{if} \ x \in \Omega_- , \\
\varepsilon_+ & \text{if} \ x \in \Omega_+ ,
\end{cases} \tag{1.2}
\]

where \( \varepsilon_- \) and \( \varepsilon_+ \) are the dielectric permittivities for the solute and solvent, respectively. (Typically, \( \varepsilon_- \approx \varepsilon_0 \) and \( \varepsilon_+ \approx 80 \varepsilon_0 \) with \( \varepsilon_0 \) the vacuum permittivity.) See Figure 1. The function \( f : \Omega \to \mathbb{R} \) represents the charge density of solute molecules, while the term \(-B' (\phi_T)\) describes the ensemble-averaged charge density of mobile ions in the solvent. The function \( B : \mathbb{R} \to \mathbb{R} \) is given by

\[
B (\phi) = \beta^{-1} \sum_{j=1}^{M} c_j^\infty \left( e^{-\beta q_j \phi} - 1 \right), \tag{1.3}
\]

where \( M \geq 1 \) is the number of ionic species, \( \beta^{-1} = k_B T \) with \( k_B \) the Boltzmann constant and \( T \) temperature, \( q_j = Z_j e \) with \( e \) the elementary charge, and \( c_j^\infty \) and \( Z_j \) are the bulk ionic concentration and valence of ions of the \( j \)th species. We note that different forms of the function \( B \) can be used for different models; cf. e.g., \([5, 17, 18, 19]\). The equilibrium electrostatic potential \( \phi_T \), the optimal boundary \( \Gamma \), and the VISM free energy depend on the form of \( B \) and the parameters used in defining \( B \). A commonly used boundary condition for the electrostatic potentials is \( \phi = g \) on \( \partial \Omega \) with \( g : \partial \Omega \to \mathbb{R} \) a given function.

![Figure 1: A schematic diagram of charged molecules immersed in an aqueous solvent. The region of solvation \( \Omega \) is divided by the solute-solvent interface (i.e., dielectric boundary) \( \Gamma \) into the solute region \( \Omega_- \) and the solvent region \( \Omega_+ \). The solute region \( \Omega_- \), which can have multiple connected subregions, contains all the solute atoms \( x_i \) carrying partial charges \( Q_i \) (i = 1, . . . , N). The unit normal \( n \) at \( \Gamma \) points from \( \Omega_- \) to \( \Omega_+ \).](image)

The PBE (1.1) is the Euler–Lagrange equation of the classical PB electrostatic energy functional applied to the continuum solution \([6, 13, 14, 19, 20, 23, 32]\)

\[
I_R [\phi] = \int_\Omega \left[ -\frac{\varepsilon R}{2} |\nabla \phi|^2 + f \phi - \chi_+ B (\phi) \right] \, dx \quad \forall \phi \in H^1_0 (\Omega), \tag{1.4}
\]
where 

$$H_g^1(\Omega) = \{ \phi \in H^1(\Omega) : \phi = g \text{ on } \partial \Omega \}.$$ 

This functional is concave and maximized to yield the equilibrium electrostatic potential \( \phi_{\Gamma} \), which is the solution to the PBE, and the corresponding electrostatic energy \( E_{\text{ele}}[\Gamma] = I_{\Gamma}[\phi_{\Gamma}] \). We refer to [6, 8] for discussions on the maximization instead of minimization of the electrostatic energy functional for equilibrium electrostatics.

An iterative method is often used to minimize numerically the VISM solvation free-energy functional. In each step of the iteration, one solves the PBE (1.1) or maximizes the PB functional (1.4). Maximizing the electrostatic energy and then minimizing the total VISM solvation free energy may possibly develop instabilities if there are not enough steps for such maximization or minimization. It is therefore natural to ask if the electrostatics can be determined by minimizing a convex energy functional. Motivated by such a question, here we develop an alternative approach to the electrostatics for VISM, based on the concept of the Legendre-transformed Poisson–Boltzmann (LTPB) electrostatic energy [27] (cf. also [4, 8, 28, 30]). For a given dielectric boundary \( \Gamma \), the LTPB energy functional is given by [8]

$$J_{\Gamma}[D] = \int_{\Omega} \left[ \frac{1}{2\varepsilon_{\Gamma}} |D|^2 + \chi_+ B^*(f - \nabla \cdot D) \right] dx + \int_{\partial \Omega} g(D \cdot n) dS$$  \(1.5\)

for all dielectric displacements \( D : \Omega \to \mathbb{R}^3 \) that are constrained by Gauss’ law (in the differential form)

$$\nabla \cdot D = f \quad \text{in } \Omega_-, \quad \nabla \cdot D = f \quad \text{in } \Omega_-,$$ \(1.6\)

where \( B^* \) is the Legendre transform of \( B \) and \( n \) is the unit exterior normal at \( \partial \Omega \). We recall for \( \xi \in \mathbb{R} \) that [33, 42]

$$B^*(\xi) = \sup_{a \in \mathbb{R}} [a\xi - B(a)] = s\xi - B(s) \quad \text{with } B'(s) = \xi, \quad \text{and } B''(\xi) = s.$$ \(1.7\)

Our main results are the following:

(1) We construct the LTPB electrostatic energy functional with the constraint for both the case of a continuum solute charge density represented by an integrable function (cf. (1.5)) and that of a discrete charge density (or point charges) described by a linear combination of Dirac masses. We prove the duality between the classical PB and the LTPB functionals. For a continuum charge density \( f \in L^2(\Omega) \), this duality is max \( \phi_{\Gamma} \in H_g^1(\Omega) \) \( I_{\Gamma}[\phi] = \min_{D \in V_{\Gamma,f}} J_{\Gamma}[D] \), and the unique maximizer \( \phi_{\Gamma} \) of \( I_{\Gamma} \) over \( H_g^1(\Omega) \) and the unique minimizer \( D_{\Gamma} \) of \( J_{\Gamma} \) over \( V_{\Gamma,f} \) are related by \( D_{\Gamma} = -\varepsilon_{\Gamma} \nabla \phi_{\Gamma} \), where

$$V_{\Gamma,f} = \{ D \in H(\text{div}, \Omega) : \nabla \cdot D = f \text{ in } \Omega_- \}, \quad \nabla \cdot D = f \text{ in } \Omega_-,$$ \(1.8\)

$$H(\text{div}, \Omega) = \{ D \in [L^2(\Omega)]^3 : \nabla \cdot D \in L^2(\Omega) \}.$$ \(1.9\)

(2) To minimize numerically the LTPB functional, we propose a penalty method. For the case of a continuum charge density \( f \in L^2(\Omega) \), this method amounts minimizing the penalized functional

$$J_{\Gamma, \mu}[D] = J_{\Gamma}[D] + \frac{1}{2\mu} \int_{\Omega_-} |\nabla \cdot D - f|^2 dx \quad \forall D \in H(\text{div}, \Omega),$$ \(1.10\)
without the constraint, where \( \mu > 0 \) is a penalty parameter and \( \chi_- \) is the characteristic function of \( \Omega_- \). We prove that, as \( \mu \to 0 \), the minimizer and minimum value of the penalized functional \( J_{\Gamma, \mu} \) converge to those for the functional \( J_{\Gamma} : V_{\Gamma, f} \to \mathbb{R} \), respectively. Such convergence is numerically verified.

(3) We incorporate the LTPB electrostatics into the VISM, and derive the dielectric boundary force \( -\delta_{\Gamma}(\min_D J_{\Gamma}[D]) \) using the minimizing dielectric displacement \( D_{\Gamma} \in V_{\Gamma, f} \). We also construct a min-min algorithm and a max-min algorithm to minimize numerically the total VISM free energy with the LTPB and PB electrostatics, respectively. The convergence of the min-min optimization algorithm is shown.

(4) We present an analysis of the duality and the penalty method for a simplified radially symmetric system resulting from the application of VISM to the solvation of a single ion. We also provide a new and direct derivation of the dielectric boundary force for a similar and reduced one-dimensional system. Moreover, we report extensive numerical results on the solvation of a single ion to show that the LTPB formulation with the min-min algorithm performs better than the PB formulation with the max-min algorithm and that the VISM-LTPB predicts accurately the solvation free energy of single ions.

We remark that our results can be directly extended to some size-modified PB and LTPB electrostatics with a general convex function \( B \) [3, 5, 12, 15, 16, 17, 18, 19, 21, 25, 37, 41].

The rest of this paper is organized as follows: In section 2, we construct the LTPB electrostatic functionals and prove the duality of the LTPB and the PB functionals. We also propose and prove the convergence of a penalty method for minimizing the LTPB energy functional and present some numerical results. In section 3, we apply the LTPB theory to the variational implicit solvation and derive the dielectric boundary force. We also design a min-min algorithm and prove its convergence for minimizing the VISM-LTPB functional. Numerical results for the solvation of an ion are presented. Finally, in section 4, we draw conclusions of our findings. In Appendix, we give a new and direct derivation of the dielectric boundary force for a one-dimensional model system.

## 2 The LTPB Electrostatics with a Dielectric Boundary

We assume the following:

(A1) All \( \Omega, \Omega_-, \Omega_+ \) are smooth and bounded open sets in \( \mathbb{R}^3 \), \( \Gamma = \partial \Omega_- \), and all \( x_i \in \Omega_- \) and \( Q_i \in \mathbb{R} \) \((i = 1, \ldots, N)\) are given; cf. Figure 1;

(A2) Both \( \varepsilon_- \) and \( \varepsilon_+ \) are given, distinct positive numbers, and \( \varepsilon_{\Gamma} \) is defined by \( \varepsilon_{\Gamma} = \varepsilon_{\pm} \) in \( \Omega_{\pm} \);

(A3) The function \( B : \mathbb{R} \to \mathbb{R} \) is smooth, strictly convex, and uniquely minimized at 0 with \( B(0) = 0 \). Moreover, \( B(\pm \infty) = \infty \); (An example of such a function is \( B(s) = \cosh(s) - 1 \)).

(A4) The function \( f \in L^2(\Omega) \) is given, and is smooth, e.g., \( f \in H^1(\Omega) \). The boundary value \( g : \partial \Omega \to \mathbb{R} \) (cf. (1.4) and (1.5)) is the trace of some function, also denoted \( g \), in \( W^{1, \infty}(\Omega) \).

We note that the function \( B : \mathbb{R} \to \mathbb{R} \) defined in (1.3) and those model the ionic size effect in the size-modified PB theory [18, 19, 21, 41] all satisfy the assumption (A3). We also recall that the space \( H(\text{div}, \Omega) \) (cf. (1.9)) is a Hilbert space with respect to the inner product

\[
\langle D_1, D_2 \rangle = \int_{\Omega} [D_1 \cdot D_2 + (\nabla \cdot D_1)(\nabla \cdot D_2)] \, dx.
\]
Moreover, $D \cdot n \in L^2(\partial \Omega)$ if $D \in H(\text{div}, \Omega)$ and [36]

$$
\int_\Omega (\nabla \cdot D) u \, dx = - \int_\Omega D \cdot \nabla u \, dx + \int_{\partial \Omega} (D \cdot n) u \, dS \quad \forall u \in H^1(\Omega). \tag{2.1}
$$

2.1 The electrostatic energy functionals and the duality

Case 1. A continuum charge density. For this case, the Poisson–Boltzmann (PB) and the Legendre-transformed Poisson–Boltzmann (LTPB) functionals $I_\Gamma : H^1_0(\Omega) \to \mathbb{R} \cup \{-\infty\}$ and $J_\Gamma : V_\Gamma \to \mathbb{R} \cup \{\infty\}$ are defined in (1.4) and (1.5), respectively, and their properties are summarized in the next theorem. We denote $[u]_\Gamma = u|_{\Omega_+} - u|_{\Omega_-}$ on $\Gamma$ for any $u : \Omega \to \mathbb{R}$ when the traces are defined.

**Theorem 2.1.** (1) The PB functional $I_\Gamma : H^1_0(\Omega) \to \mathbb{R} \cup \{-\infty\}$ admits a unique maximizer $\phi_\Gamma \in H^1_0(\Omega)$. Moreover, $\phi_\Gamma \in L^\infty(\Omega)$, $\phi_\Gamma|_{\Omega_{\pm}} \in H^2(\Omega_{\pm})$, and $[\epsilon_\Gamma \partial_n \phi_\Gamma]|_\Gamma = 0$, and $\phi_\Gamma$ is the unique weak solution in $H^1_0(\Omega)$ to the PB equation (1.1).

(2) Let $D_\Gamma = -\epsilon_\Gamma \nabla \phi_\Gamma$. Then, $D_\Gamma \in V_\Gamma$ and it is the unique minimizer of the LTPB functional $J_\Gamma : V_\Gamma \to \mathbb{R} \cup \{\infty\}$. Moreover, $[D_\Gamma \cdot n]|_\Gamma = 0$ and $B^*(f - \nabla \cdot D_\Gamma) = \phi_\Gamma$ in $\Omega_+$.

(3) Duality: $\max_{\phi \in H^1_0(\Omega)} I_\Gamma[\phi] = \min_{D \in \mathcal{V}_{\Gamma}} J_\Gamma[D].$

**Proof.** (1) By Poincaré’s inequality, we have $\sup_{\phi \in H^1_0(\Omega)} I_\Gamma[\phi] < \infty$. The existence and uniqueness of a maximizer $\phi_\Gamma$ for $I_\Gamma : H^1_0(\Omega) \to \mathbb{R} \cup \{-\infty\}$ can be obtained by the direct method in the calculus of variations, using the strict convexity of $B$. A comparison argument leads to $\phi_\Gamma \in L^\infty(\Omega)$ [20]. Routine calculations then imply that the maximizer $\phi_\Gamma$ satisfies the PB equation (PBE) (1.1), which is the Euler–Lagrange equation for the functional $I_\Gamma$, and that $[\epsilon_\Gamma \partial_n \phi_\Gamma]|_\Gamma = 0$. The regularity of $\phi_\Gamma$ follows from existing results of solution regularity for elliptic equations; cf. [20, 23].

(2) For any $\phi \in H^1_0(\Omega)$ and any $D \in V_\Gamma$, we have by (2.1) that

$$
I_\Gamma[\phi] \leq \int_\Omega \left[ -\frac{\epsilon_\Gamma}{2} |\nabla \phi|^2 + f \phi - \chi_+ B(\phi) + \frac{1}{2\epsilon_\Gamma} |\epsilon_\Gamma \nabla \phi + D|^2 \right] dx
$$

$$
= \int_\Omega \left[ \left| \frac{D}{2\epsilon_\Gamma} \right|^2 + f \phi - \chi_+ B(\phi) + \nabla \phi \cdot D \right] dx
$$

$$
= \int_\Omega \left[ \left| \frac{D}{2\epsilon_\Gamma} \right|^2 + \chi_+ (f - \nabla \cdot D - B(\phi)) \right] dx + \int_{\partial \Omega} g(D \cdot n) \, dS
$$

$$
\leq \int_\Omega \left[ \left| \frac{D}{2\epsilon_\Gamma} \right|^2 + \chi_+ B^*(f - \nabla \cdot D) \right] dx + \int_{\partial \Omega} g(D \cdot n) \, dS
$$

$$
= J_\Gamma[D].
$$

Note by (1.1) that $D_\Gamma = -\epsilon_\Gamma \nabla \phi_\Gamma \in V_\Gamma$. Setting $\phi = \phi_\Gamma$ and $D = D_\Gamma$ and noting by (1.1) that $f - \nabla \cdot D_\Gamma = B'(\phi_\Gamma)$ and hence $B^*(f - \nabla \cdot D_\Gamma) = \phi_\Gamma(f - \nabla \cdot D_\Gamma) - B(\phi_\Gamma)$ in $\Omega_+$, we have $I_\Gamma[\phi_\Gamma] = J_\Gamma[D_\Gamma]$. Thus, $D_\Gamma$ is a minimizer of $J_\Gamma$ over $V_\Gamma$. It is unique since $J_\Gamma$ is strictly convex over $V_\Gamma$. Since $[\epsilon_\Gamma \partial_n \phi_\Gamma]|_\Gamma = 0$, we have $[D_\Gamma \cdot n]|_\Gamma = 0$. By the PBE (1.1), we also have $f - \nabla \cdot D_\Gamma = \chi_+ B(\phi_\Gamma)$ in $\Omega_+$. Hence, by the property of Legendre transforms, $B^*(f - \nabla \cdot D_\Gamma) = \phi_\Gamma$ in $\Omega_+$.

(3) This follows from $I_\Gamma[\phi_\Gamma] = \max_{\phi \in H^1_0(\Omega)} I_\Gamma[\phi] \leq \min_{D \in \mathcal{V}_{\Gamma}} J_\Gamma[D] = J_\Gamma[D_\Gamma] = I_\Gamma[\phi_\Gamma].$ \hfill \[2.1\]
Case 2. A discrete charge density. The equilibrium electrostatic potential, now denoted \( \hat{\phi}_\Gamma \), is the weak solution to the boundary-value problem of the PBE with point charges [19, 23, 38, 40]

\[
\begin{cases}
\nabla \cdot \varepsilon_\Gamma \nabla \hat{\phi}_\Gamma - \chi_+ B' (\hat{\phi}_\Gamma) = - \sum_{i=1}^N Q_i \delta_{x_i} & \text{in } \Omega, \\
\hat{\phi}_\Gamma = g & \text{on } \partial \Omega,
\end{cases}
\]  
(2.2)

where \( \delta_a \) denotes the Dirac mass concentrated on \( a \in \mathbb{R}^3 \). The electrostatic energy is given by [19, 23, 40]

\[
E_{\text{ele}}[\Gamma] = \frac{1}{2} \sum_{i=1}^N Q_i (\hat{\phi}_\Gamma - \hat{\phi}_C)(x_i) + \int_{\Omega} \left[ \frac{1}{2} \hat{\phi}_\Gamma B' (\hat{\phi}_\Gamma) - B(\hat{\phi}_\Gamma) \right] dx, 
\]  
(2.3)

where \( \hat{\phi}_C \) is the Coulomb potential: \( \hat{\phi}_C (x) = \sum_{i=1}^N Q_i / (4 \pi \varepsilon_- |x - x_i|) \). Note that we do not include an extra term in \( B \) as we can derive the energy form by minimizing a continuum electrostatic free-energy functional of ionic concentrations using different boundary conditions (e.g., the homogeneous Neumann boundary condition) for electrostatic potentials. The boundary value \( g \) in (2.2) is an approximation of that of the equilibrium electrostatic potential; cf. [19, 22, 23, 24, 40]. Following [19, 23], we express the electrostatic energy using integrals that are mathematically more convenient to handle:

\[
E_{\text{ele}}[\Gamma] = - \int_{\Omega} \left[ \frac{\varepsilon_- - \varepsilon_+}{2} \nabla \hat{\phi}_\Gamma \cdot \nabla \hat{\phi}_\infty + \nabla \hat{\phi}_\infty \cdot \nabla \hat{\phi}_\Gamma + \frac{1}{2} \sum_{i=1}^N Q_i (\hat{\phi}_\infty - \hat{\phi}_C)(x_i) \right] dx, 
\]  
(2.4)

\[
A_\Gamma := \frac{\varepsilon_- - \varepsilon_+}{2} \int_{\Omega} \nabla \hat{\phi}_\infty \cdot \nabla \hat{\phi}_\Gamma dx + \frac{1}{2} \sum_{i=1}^N Q_i (\hat{\phi}_\infty - \hat{\phi}_C)(x_i). 
\]  
(2.5)

Here, \( \hat{\phi}_{\Gamma, \infty} \) is defined by \( - \nabla \cdot \varepsilon_\Gamma \nabla \hat{\phi}_{\Gamma, \infty} = \sum_{i=1}^N Q_i \delta_{x_i} \) in \( \Omega \) and \( \hat{\phi}_{\Gamma, \infty} = g \) on \( \partial \Omega \), and both \( \hat{\phi}_0 \) and \( \hat{\phi}_\infty \) are solutions to \( - \varepsilon_- \Delta u = \sum_{i=1}^N Q_i \delta_{x_i} \) in \( \Omega \) with \( \hat{\phi}_0 = 0 \) and \( \hat{\phi}_\infty = g \) on \( \partial \Omega \), respectively; cf. [23]. Note that \( \hat{\phi}_\infty - \hat{\phi}_C \) is harmonic in \( \Omega_- \) so each \( (\hat{\phi}_\infty - \hat{\phi}_C)(x_i) \) \( (1 \leq i \leq N) \) is well defined as the limit as \( x \to x_i \).

We define the PB energy functional for the case of point charges \( \hat{I}_\Gamma : \hat{\phi}_{\Gamma, \infty} + H^1_0(\Omega) \to \mathbb{R} \cup \{-\infty\} \) by

\[
\hat{I}_\Gamma[\phi] = - \int_{\Omega} \left[ \frac{\varepsilon_+}{2} |\nabla (\phi - \hat{\phi}_{\Gamma, \infty})|^2 + \chi_+ B(\phi) \right] dx + A_\Gamma \quad \forall \phi \in \hat{\phi}_{\Gamma, \infty} + H^1_0(\Omega). 
\]  
(2.6)

Note that \( \hat{I}_\Gamma[\hat{\phi}_\Gamma] = E_{\text{ele}}[\Gamma] \) is the electrostatic energy. Note also that \( \phi \in \hat{\phi}_{\Gamma, \infty} + H^1_0(\Omega) \) if and only if \( \phi \in \hat{\phi}_C + H^1_0(\Omega) \) with \( h = g - \hat{\phi}_C \). Let \( V_{\Gamma, 0} \) be defined by (1.8) with \( f = 0 \). We define the Legendre-transformed PB (LTPB) functional \( \hat{J}_\Gamma : V_{\Gamma, 0} \to \mathbb{R} \cup \{\infty\} \) by

\[
\hat{J}_\Gamma[D] = \int_{\Omega} \left\{ \frac{1}{2\varepsilon_\Gamma} |D|^2 dx + \chi_+ \left[ B^* (-\nabla \cdot D) + \hat{\phi}_{\Gamma, \infty} \nabla \cdot D \right] \right\} dx + A_\Gamma \quad \forall D \in V_{\Gamma, 0}. 
\]  
(2.7)

**Theorem 2.2.** (1) The PB functional \( \hat{I}_\Gamma : \hat{\phi}_{\Gamma, \infty} + H^1_0(\Omega) \to \mathbb{R} \cup \{-\infty\} \) admits a unique maximizer \( \hat{\phi}_\Gamma \). Moreover, \( \hat{\phi}_\Gamma - \hat{\phi}_{\Gamma, \infty} \in L^\infty(\Omega) \), \( (\hat{\phi}_\Gamma - \hat{\phi}_{\Gamma, \infty})|_{\Omega_\pm} \in H^2(\Omega_\pm) \), and \( \|[\varepsilon_\Gamma \partial_a \hat{\phi}_\Gamma]|_{\Gamma} = 0 \), and \( \hat{\phi}_\Gamma \) is the unique weak solution to the boundary-value problem of the PBE (2.2).
(2) Let $\hat{D}_Γ = -\varepsilon_Γ \nabla (\hat{ϕ}_Γ - \hat{ϕ}_{Γ,∞})$. Then, $\hat{D}_Γ \in V_{Γ,0}$ and it is the unique minimizer of the LTPB functional $\hat{J}_Γ : V_{Γ,0} \to \mathbb{R} \cup \{\infty\}$. Moreover, $B^*(-\nabla \cdot \hat{D}_Γ) = \hat{ϕ}_Γ$ in $Ω_+$.

(3) Duality: $\max_{\phi \in \hat{ϕ}_{Γ,∞} + H^1(Ω)} \hat{I}_Γ[\phi] = \min_{D \in V_{Γ,0}} \hat{J}_Γ[D]$.

Proof. The proof of part (1) and part (3) is similar to that for Theorem 2.1. So, we only prove part (2). Let $\phi \in \hat{ϕ}_{Γ,∞} + H^1(Ω)$ and $D \in V_{Γ,0}$. Then,

$$\hat{I}_Γ[\phi] \leq \int_Ω \left[ \frac{-\varepsilon_Γ}{2} |\nabla (\phi - \hat{ϕ}_{Γ,∞})|^2 + \frac{1}{2\varepsilon_Γ} |\varepsilon_Γ \nabla (\phi - \hat{ϕ}_{Γ,∞}) + D|^2 - \chi_+ B(\phi) \right] dx + A_Γ
$$

$$= \int_Ω \left[ \frac{|D|^2}{2\varepsilon_Γ} + \nabla \left( \phi - \hat{ϕ}_{Γ,∞} \right) \cdot D - \chi_+ B(\phi) \right] dx + A_Γ
$$

$$= \int_Ω \left[ \frac{|D|^2}{2\varepsilon_Γ} - \left( \phi - \hat{ϕ}_{Γ,∞} \right) \nabla \cdot D - \chi_+ B(\phi) \right] dx + A_Γ
$$

$$= \int_Ω \left\{ \frac{|D|^2}{2\varepsilon_Γ} + \chi_+ \left[ \phi(-\nabla \cdot D) - B(\phi) + \hat{ϕ}_{Γ,∞} \nabla \cdot D \right] \right\} dx + A_Γ
$$

$$\leq \int_Ω \left\{ \frac{1}{2\varepsilon_Γ} |D|^2 + \chi_+ \left[ B^*(-\nabla \cdot D) + \hat{ϕ}_{Γ,∞} \nabla \cdot D \right] \right\} dx + A_Γ
$$

$$= \hat{J}_Γ[D].$$

By (2.2) and the definition of $\hat{ϕ}_{Γ,∞}$, we have $\hat{D}_Γ = -\varepsilon_Γ \nabla (\hat{ϕ}_Γ - \hat{ϕ}_{Γ,∞}) \in V_{Γ,0}$. Setting $\phi = \hat{ϕ}_Γ$ and $D = \hat{D}_Γ$ and noting that $-\nabla \cdot \hat{D}_Γ = B'(\hat{ϕ}_Γ)$ and hence $B^*(-\nabla \cdot \hat{D}_Γ) = (-\nabla \cdot \hat{D}_Γ)\hat{ϕ}_Γ - B(\hat{ϕ}_Γ)$ in $Ω_+$, we have $\hat{I}_Γ[\hat{ϕ}_Γ] = \hat{J}_Γ[\hat{D}_Γ]$. Thus, $\hat{D}_Γ$ is a minimizer of $\hat{J}_Γ$ over $V_{Γ,0}$. It is unique since $\hat{J}_Γ$ is strictly convex over $V_{Γ,0}$. Finally, it follows from the property of Legendre transforms that $B^*(-\nabla \cdot \hat{D}_Γ) = \hat{ϕ}_Γ$ in $Ω_+$.

### 2.2 A penalty method

Let $μ > 0$. Recall that $J_{Γ,μ}$ is defined in (1.10). Similarly, we define $\hat{J}_{Γ,μ} : H(\text{div}, Ω) \to \mathbb{R} \cup \{+\infty\}$ by

$$\hat{J}_{Γ,μ}[D] = \hat{J}_Γ[D] + \frac{1}{2μ} \int_{Ω_-} (\nabla \cdot D)^2 dx. \tag{2.8}$$

**Theorem 2.3.** For each $μ > 0$, the functional $J_{Γ,μ}(\text{resp. } \hat{J}_{Γ,μ}) : H(\text{div}, Ω) \to \mathbb{R} \cup \{+\infty\}$ admits a unique minimizer $D_{Γ,μ}$ (resp. $\hat{D}_{Γ,μ}$) in $H(\text{div}, Ω)$ and $\min_{D \in H(\text{div}, Ω)} J_{Γ,μ}[D] \to \min_{D \in V_{Γ,0}} J_{Γ,μ}[D]$ as $μ \to 0$, where $D_Γ = \arg\min_{D \in V_{Γ,0}} J_Γ[D]$ (resp. $\hat{D}_Γ = \arg\min_{D \in V_{Γ,0}} \hat{J}_Γ[D]$).

Proof. We only consider $J_{Γ,μ}$ and $J_Γ$ as the proof for $\hat{J}_{Γ,μ}$ and $\hat{J}_Γ$ is similar. Let $μ > 0$. We define $I_{Γ,μ} : H^1(Ω) \to \mathbb{R} \cup \{-∞\}$ by

$$I_{Γ,μ}[ϕ] = I_Γ[ϕ] - \frac{μ}{2} \int_{Ω_-} ϕ^2 dx = \int_Ω \left[ \frac{-\varepsilon_Γ}{2} |\nabla ϕ|^2 + fϕ - χ_+ B(ϕ) - \frac{χ_+ B(ϕ)}{2} ϕ^2 \right] dx. \tag{2.9}$$

7
Similar to the proof of Theorem 2.1, the functional $I_{\Gamma, \mu} : H^1_g(\Omega) \to \mathbb{R} \cup \{-\infty\}$ admits a unique maximizer $\phi_{\Gamma, \mu} \in L^\infty(\Omega)$ and it is the unique weak solution in $H^1_g(\Omega)$ to the Euler–Lagrange equation

$$-\nabla \cdot \varepsilon_\Gamma \nabla \phi_{\Gamma, \mu} + \chi_+ B'(\phi_{\Gamma, \mu}) + \mu \chi_- \phi_{\Gamma, \mu} = f \quad \text{in } \Omega. \quad (2.10)$$

We show that $\phi_{\Gamma, \mu} \to \phi_\Gamma$ in $H^1(\Omega)$ and $I_{\Gamma, \mu}[\phi_{\Gamma, \mu}] \to I_\Gamma[\phi_\Gamma]$ as $\mu \to 0$, where $\phi_\Gamma$ is the unique maximizer of $I_\Gamma : H^1_g(\Omega) \to \mathbb{R} \cup \{-\infty\}$. It suffices to show that for any sequence $\mu_k \searrow 0$, there is a subsequence, not relabelled, such that $\phi_{\Gamma, \mu_k} \to \phi_\Gamma$ in $H^1(\Omega)$ and $I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu_k}] \to I_\Gamma[\phi_\Gamma]$ as $k \to \infty$.

Let $\hat{\gamma} \in H^1_g(\Omega)$ be such that $\hat{\gamma} = 0$ in $\Omega_-$. Then $I_{\Gamma, \mu}[\phi_{\Gamma, \mu}] = \max_{\phi \in H^1(\Omega)} I_{\Gamma, \mu}[\phi] \geq I_{\Gamma, \mu}[\hat{\gamma}] = I_\Gamma[\hat{\gamma}] > -\infty$. It then follows from the definition of $I_{\Gamma, \mu}$ and Poincaré’s inequality that

$$\sup_{\mu > 0} \|\phi_{\Gamma, \mu}\|_{H^1(\Omega)} < \infty. \quad (2.11)$$

Now for any $\mu_k \searrow 0$, there exists a subsequence of $\{\phi_{\Gamma, \mu_k}\}$, not relabelled, and some $\tilde{\phi}_\Gamma \in H^1(\Omega)$ such that $\phi_{\Gamma, \mu_k} \rightharpoonup \tilde{\phi}_\Gamma$ in $H^1(\Omega)$. ($\rightharpoonup$ denotes the weak convergence.) Clearly, $\phi_\Gamma \in H^1(\Omega)$. By the convexity of $-I_\Gamma$, $\limsup_{k \to \infty} I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu_k}] \leq I_\Gamma[\tilde{\phi}_\Gamma]$. This and the fact $I_{\Gamma, \mu_k}[\phi_\Gamma] \leq I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu_k}] \leq I_\Gamma[\phi_{\Gamma, \mu_k}]$ imply that

$$I_{\Gamma, \mu_k} = \lim_{k \to \infty} I_{\Gamma, \mu_k}[\phi_\Gamma] \leq \liminf_{k \to \infty} I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu_k}] \leq \liminf_{k \to \infty} I_\Gamma[\phi_{\Gamma, \mu_k}] \leq \limsup_{k \to \infty} I_\Gamma[\phi_{\Gamma, \mu}] \leq I_\Gamma[\phi_\Gamma].$$

Thus, $I_\Gamma[\phi_\Gamma] = I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu}] \to I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu}] = I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu}]$ and $\tilde{\phi}_\Gamma = \phi_\Gamma$ by the uniqueness of maximizer of $I_\Gamma$. Hence, $I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu}] \to I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu}] = I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu}]$.

We now prove the strong convergence $\phi_{\Gamma, \mu} \to \phi_\Gamma$ in $H^1(\Omega)$. Denote for each $k \geq 1$:

$$a_k = \int_\Omega \frac{\varepsilon_\Gamma}{2} |\nabla \phi_{\Gamma, \mu}|^2 - \frac{\varepsilon_\Gamma}{2} |\nabla \phi_\Gamma|^2 \, dx \quad \text{and} \quad b_k = \int_{\Omega_+} [B(\phi_{\Gamma, \mu_k}) - B(\phi_\Gamma)] \, dx.$$

Passing to a further subsequence if necessary, we have by the weak convergence $\phi_{\Gamma, \mu_k} \rightharpoonup \phi_\Gamma$ in $H^1(\Omega)$ that $\phi_{\Gamma, \mu_k} \to \phi_\Gamma$ in $L^2(\Omega)$ and $\phi_{\Gamma, \mu_k} \to \phi_\Gamma$ a.e. in $\Omega$. These, together with the energy convergence $I_{\Gamma, \mu_k}[\phi_{\Gamma, \mu_k}] \to I_\Gamma[\phi_\Gamma]$ as $k \to \infty$ and the bound (2.11), imply that $a_k + b_k \to 0$ as $k \to \infty$. But $\liminf_{k \to \infty} a_k \geq 0$ as $\phi_{\Gamma, \mu_k} \rightharpoonup \phi_\Gamma$ in $H^1(\Omega)$ and $\liminf_{k \to \infty} b_k \geq 0$ by Fatou’s lemma. Therefore, $0 = \lim_{k \to \infty} (a_k + b_k) \geq \liminf_{k \to \infty} a_k + \liminf_{k \to \infty} b_k \geq 0$.

Hence $\liminf_{k \to \infty} a_k = 0$. Passing to a further subsequence if necessary and without relabelling, we have $a_k \to 0$ as $k \to \infty$. This and the weak convergence $\phi_{\Gamma, \mu_k} \rightharpoonup \phi_\Gamma$ in $H^1(\Omega)$, together with the identity

$$\|\nabla \phi_{\Gamma, \mu} - \nabla \phi_\Gamma\|^2 = \|\nabla \phi_{\Gamma, \mu}\|^2 - \|\nabla \phi_\Gamma\|^2 - 2 \int_\Omega \nabla \phi_\Gamma \cdot \nabla (\phi_{\Gamma, \mu} - \phi_\Gamma) \, dx,$$

imply that $\nabla \phi_{\Gamma, \mu_k} \to \nabla \phi_{\Gamma, \mu}$ in $L^2(\Omega)$ and consequently that $\phi_{\Gamma, \mu} \to \phi_\Gamma$ in $H^1(\Omega)$.

Finally, set $D_{\Gamma, \mu} = -\varepsilon_\Gamma \nabla \phi_{\Gamma, \mu}$. By (2.10), $D_{\Gamma, \mu} \in H(\text{div}, \Omega)$ and $\nabla \cdot D_{\Gamma, \mu} = f - \chi_+ B'(\phi_{\Gamma, \mu}) - \mu \chi_- \phi_{\Gamma, \mu}$ in $\Omega$. Moreover, since the Legendre transform of $s \mapsto ms^2/2$ is $\xi \mapsto \xi^2/(2\mu)$, we see that $D_{\Gamma, \mu}$ is the unique minimizer of $J_{\Gamma, \mu}$ over $H(\text{div}, \Omega)$ and $J_{\Gamma, \mu}[D_{\Gamma, \mu}] = I_{\Gamma, \mu}[\phi_{\Gamma, \mu}]$ (cf. the proof of Theorem 2.1). Thus, $D_{\Gamma, \mu} \to D_\Gamma$ in $H(\text{div}, \Omega)$ and $\min_{D \in H(\text{div}, \Omega)} J_{\Gamma, \mu}[D] \to \min_{D \in V_{\text{tr}, \Gamma}} J_\Gamma[D]$. □
2.3 Numerical results

We choose \( \Omega = (-1, 1)^3 \), \( \Gamma = \{x \in \mathbb{R}^3 : |x| = 1/2\} \), \( \varepsilon_- = \varepsilon_0, \varepsilon_+ = 78\varepsilon_0 \), \( f = 1 \) in \( \Omega \), and \( g = 0 \) on \( \partial\Omega \), and consider \( B(s) = s^2/2 \) and \( B(s) = \cosh(s) - 1 \). We cover \( \Omega = [-1, 1]^3 \) with a uniform finite-difference grid of size \( h = 2L/N \), where \( N + 1 \) is the number of grid points in each coordinate direction, and use the central differencing and trapezoidal rule to discretize the energy functionals. The nonlinear conjugate gradient method is used to minimize or maximize numerically the resulting convex and concave functionals, respectively. We first maximize the discretized functional \( I_\Gamma \) with a very fine grid to obtain a numerical maximizer \( \phi_{\text{exact}} \), and calculate \( D_{\text{exact}} = -\varepsilon_\Gamma \nabla \phi_{\text{exact}} \) and use it as the “exact” solution. We then choose several values of \( N \) and \( \mu \). For each pair of the chosen \( N \) and \( \mu \), we minimize numerically the discretized functional \( J_{\Gamma,\mu} \) to obtain a numerical minimizer \( D_{\mu,N} \). To test how the constraint \( \nabla \cdot D = f \) in \( \Omega_- \) is satisfied, we define the penalty error

\[
\text{PE}(\mu, N) := \|\nabla \cdot D_{\mu,N} - f\|^2_{L^2(\Omega_-)}.
\]

Figure 2 (Top) shows that for a fixed \( \mu > 0 \) the error decreases with the increase of \( N \), the number of grid points in one direction. For a large value of \( \mu > 0 \), such error decreasing saturates as \( N \) increases due to the penalty error with the fixed \( \mu \). Moreover, for a fixed \( N \), the error decreases as \( \mu \) decreases. Figure 2 (Bottom) indicates that \( (1/2\mu)\text{PE}(\mu, N) = O(\mu) \) as \( \mu \to 0 \), implying that

\[
J_{\Gamma,\mu}[D_{\Gamma,\mu}] - J_{\Gamma}[D_{\Gamma}] = \frac{1}{2\mu} \|\nabla \cdot D_{\Gamma,\mu} - f\|^2_{L^2(\Omega_-)} \to 0 \quad \text{as} \quad \mu \to 0,
\]

as prediction by Theorem 2.3.

3 Application to Variational Implicit Solvation

3.1 Solvation free energy and the dielectric boundary force

In the variational implicit-solvent model (VISM) (cf. Figure 1), the solvation free-energy functional of dielectric boundaries is given by \([10, 11, 35, 40]\)

\[
F[\Gamma] = P_0 \text{Vol}(\Omega_-) + \gamma_0 \int_\Gamma (1 - 2\tau H) \, dS + \rho_w \int_{\Omega_+} U(x) \, dV + E_{\text{ele}}[\Gamma]. \tag{3.1}
\]

Here, \( P_0 \) is the difference between the pressure outside and inside the molecular region \( \Omega_- \), \( \gamma_0 \) is the constant surface tension, \( \tau \) is the Tolman length, and \( \rho_w \) is the bulk solvent density. All \( P_0, \gamma_0, \tau, \) and \( \rho_w \) are given constants. In addition, \( H \) is the mean curvature (positive if \( \Omega_- \) is a sphere), \( U(x) = \sum_{i=1}^N U_{\text{LJ}}^{(i)}(|x - x_i|) \) with each \( U_{\text{LJ}}^{(i)} \) a Lennard-Jones (LJ) potential. The last part \( E_{\text{ele}}[\Gamma] \) is the electrostatic energy. In the classical Poisson–Boltzmann (PB) formulation, it is given by

\[
E_{\text{ele}}[\Gamma] = \begin{cases} 
\max_{\phi \in H^1_0(\Omega)} I_\Gamma[\phi] & \text{(for a continuum charge density; cf. (1.4))}, \\
\max_{\phi \in H^1_0(\Omega)} \hat{I}_\Gamma[\phi] & \text{(for point charges; cf. (2.6))}.
\end{cases} \tag{3.2}
\]
Figure 2: The relative error $\|D_{\mu,N} - D_{\text{exact}}\|_{L^2(\Omega)}/\|D_{\text{exact}}\|_{L^2(\Omega)}$ vs. $N$ for several $\mu$-values (Top) and the penalty error $\text{PE}(\mu,N)$ vs. $1/(2\mu)$ for several values of $N$ (Bottom) for $B(s) = s^2/2$ (left) and $B(s) = \cosh(s) - 1$ (right).

The dielectric boundary force is the negative first variation of the total free energy with respect to the variation of the boundary $\Gamma$. This first variation is a function on $\Gamma$ and is given by

$$\delta_\Gamma F[\Gamma] = P_0 + 2\gamma_0(H - \tau K) + \rho_w U + \delta_\Gamma E_{\text{ele}}[\Gamma].$$

For the case of a continuum charge density, the variation of the electrostatic energy $\delta_\Gamma E_{\text{ele}}[\Gamma]$ is given by [20, 23]

$$\delta_\Gamma E_{\text{ele}}[\Gamma] = \frac{1}{2} \left( \frac{1}{\varepsilon_-} - \frac{1}{\varepsilon_+} \right) |\varepsilon_\Gamma \partial_n \phi_\Gamma|^2 + \frac{\varepsilon_+ - \varepsilon_-}{2} |(I - n \otimes n) \nabla \phi_\Gamma|^2 + B(\phi_\Gamma),$$

(3.3)

where $\phi_\Gamma$ is the equilibrium electrostatic potential, the solution to the boundary-value problem of the PB equation (PBE) (1.1), and $I$ is the $3 \times 3$ identity matrix. For the case of point charges, the formula is the same except $\phi_\Gamma$ should be replaced by $\hat{\phi}_\Gamma$, the solution to the boundary-value problem of PBE (2.2). Note that the force $-\delta_\Gamma E_{\text{ele}}[\Gamma]$ points from the higher to lower dielectric region [20].

Here, we propose to use the LTPB formulation for the electrostatic energy

$$E_{\text{ele}}[\Gamma] = \begin{cases} \min_{D \in V_{\Gamma,f}} J_\Gamma[D] & \text{(for a continuum charge density; cf. (1.5))}, \\ \min_{D \in V_{\Gamma,a}} \hat{J}_\Gamma[D] & \text{(for point charges; cf. (2.7))}. \end{cases}$$

(3.4)

By Theorem 2.1 and Theorem 2.2, both the PB and LTPB formulations lead to the same value of $E_{\text{ele}}[\Gamma]$ for a continuum charge density or for point charges. To numerically minimize the
total solvation energy, we use the penalized LTPB electrostatic energy functionals defined in (1.10) and (2.8), respectively. Let us denote also by $E_{\text{ele},\mu}[\Gamma]$ the minimum of $J_{\Gamma,\mu}$ or $\hat{J}_{\Gamma,\mu}$ over $H(\text{div},\Omega)$.

**Theorem 3.1.** (1) A continuum charge density. Let $D_T$ and $D_{T,\mu}$ be the minimizers of $J_{\Gamma} : V_{T,\Theta} \to \mathbb{R} \cup \{\infty\}$ and $J_{\Gamma,\mu} : H(\text{div},\Omega) \to \mathbb{R} \cup \{\infty\}$, respectively. We have

$$
\delta_T E_{\text{ele}}[\Gamma] = \frac{1}{2} \left( \frac{1}{\varepsilon_-} - \frac{1}{\varepsilon_+} \right) |D_T \cdot n|^2 + \frac{\varepsilon_+ - \varepsilon_-}{2} \left( (I - n \otimes n) \frac{D_T}{\varepsilon_T} \right)^2 
+ B \left( B^{\text{tr}}(f - \nabla \cdot D_T|_{\Omega_+}) \right) \text{ on } \Gamma,
$$

$$
\delta_T E_{\text{ele},\mu}[\Gamma] = \frac{1}{2} \left( \frac{1}{\varepsilon_-} - \frac{1}{\varepsilon_+} \right) |D_{\Gamma,\mu} \cdot n|^2 + \frac{\varepsilon_+ - \varepsilon_-}{2} \left( (I - n \otimes n) \frac{D_{\Gamma,\mu}}{\varepsilon_T} \right)^2 
+ B \left( B^{\text{tr}}(f - \nabla \cdot D_{\Gamma,\mu}|_{\Omega_+}) \right) - \frac{1}{2\mu} \left( f - \nabla \cdot D_{\Gamma,\mu}|_{\Omega_-} \right)^2 \text{ on } \Gamma,
$$

(2) Point charges. Let $\hat{D}_T$ and $\hat{D}_{T,\mu}$ be the minimizers of $\hat{J}_{\Gamma} : V_{T,\Theta} \to \mathbb{R} \cup \{\infty\}$ and $\hat{J}_{\Gamma,\mu} : H(\text{div},\Omega) \to \mathbb{R} \cup \{\infty\}$, respectively. Then, the above formulas in part (1) hold true with $\hat{D}_T$ and $\hat{D}_{T,\mu}$ replacing $D_T$ and $D_{T,\mu}$, respectively, and $f = 0$.

*Proof.* We only prove part (1) as the proof of part (2) is similar. By Theorem 2.1, $D_T = -\varepsilon_T \nabla \phi_T$, where $\phi_T = \text{argmax}_{\phi \in H^1(\Omega)} I_T[\phi]$, and $B^{\text{tr}}(f - \nabla \cdot D_T) = \phi_T$ in $\Omega_+$. Now the first formula follows from (3.3). Set $I_{\Gamma,\mu}[\phi] = I_T[\phi] - (\mu/2)\| \phi \|^2_{L^2(\Omega_-)}$. Then $I_{\Gamma,\mu} : H^1_0(\Omega) \to \mathbb{R} \cup \{-\infty\}$ admits a unique maximizer $\phi_{\Gamma,\mu}$. Moreover, $D_{\Gamma,\mu} = -\varepsilon_T \nabla \phi_{\Gamma,\mu}$ is the unique minimizer of $J_{\Gamma,\mu} : H(\text{div},\Omega) \to \mathbb{R} \cup \{\infty\}$, and $\max_{\phi \in H^1(\Omega)} I_{\Gamma,\mu}[\phi] = \min_{D \in H(\text{div},\Omega)} J_{\Gamma,\mu}[D] = E_{\text{ele},\mu}[\Gamma]$. With the same argument for deriving (3.3) (cf. [20, 23]), we obtain the formula for $\delta_T E_{\text{ele},\mu}[\Gamma] = \delta_T E_{\text{ele}}[\Gamma] - (\mu/2)\phi_{\Gamma,\mu}^2$. Since the Legendre transform of the function $s \mapsto \mu s^2/2$ is $\xi \mapsto \xi^2/(2\mu)$, we obtain the second formula by using the same argument. \hfill \Box

### 3.2 A min-min algorithm and a max-min algorithm

We apply the gradient descent method to minimize the total VISM free-energy functional (3.1). Once $\Gamma_k$ is given, we obtain the new boundary $\Gamma_{k+1} := \Gamma_k - \alpha_k \delta_T F[\Gamma_k]$, i.e., a point $x_k \in \Gamma_k$ is moved to $x_{k+1} = x_k - \alpha_k \delta_T F[\Gamma_k](x_k) \in \Gamma_{k+1}$, with a step size $\alpha_k > 0$. With the LTPB electrostatics, we propose a min-min algorithm for such minimization. For comparing the LTPB and PB formulations, we also design a max-min algorithm for minimizing the total free energy with the PB electrostatic energy. These algorithms are described only for the continuum charge density as they are similar for point charges. Moreover, for the LTPB formulation, we shall replace the LTPB functionals by their penalized versions. Note that for large-scale simulations it is desirable to have only a few iterations to get the approximate $\phi_{k+1}$ or $D_{k+1}$. Hence, in our numerical tests, we will choose small number of steps for such iterations.

#### A min-min algorithm for minimizing the VISM-LTPB functional

Given $\Gamma_k$ and $D_k$.

- Minimize $J_{\Gamma_k}$ over $V_{T,k,f}$ by an iteration method with $D_k$ as the initial guess to obtain an approximate minimizer $D_{k+1}$.
- Calculate $\delta_T E_{\text{ele}}[\Gamma_k]$ using $D_{k+1}$ and then calculate $\delta_T F[\Gamma_k]$.

- Replace $LTPB$ functionals by their penalized versions. Note that for large-scale simulations it is desirable to have only a few iterations to get the approximate $\phi_{k+1}$ or $D_{k+1}$. Hence, in our numerical tests, we will choose small number of steps for such iterations.
• Choose $\alpha_{k+1}$ and update $\Gamma_{k+1} = \Gamma_k - \alpha_{k+1}\delta F[\Gamma_k]$.

**A max-min algorithm for minimizing the VISM-PB functional.** Given $\Gamma_k$ and $\phi_k$.

- Maximize $I_{\Gamma_k}$ over $H^1_0(\Omega)$ by an iteration method with $\phi_k$ as the initial guess to obtain an approximate maximizer $\phi_{k+1}$;
- Calculate $\delta F_{\phi_k}E_{\phi_k}[\Gamma_k]$ using $\phi_{k+1}$ and then calculate $\delta F[\Gamma_k]$;
- Choose $\alpha_{k+1}$ and update $\Gamma_{k+1} = \Gamma_k - \alpha_{k+1}\delta F[\Gamma_k]$.

We now state the min-min algorithm and prove its convergence for a general optimization problem. We assume:

(a1) Both $m$ and $n$ are positive integers, and $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ are open, bounded, and convex;

(a2) The function $f \in C^2(U)$ is convex, and the function $g \in C^2(U \times V)$ is strictly convex;

(a3) For each $x \in U$, there exists a unique minimizer $y_x \in V$ (not on $\partial V$) of $g(x, \cdot) : V \to \mathbb{R}$.

We define $F : U \to \mathbb{R}$ and $\bar{F} : U \times V \to \mathbb{R}$, respectively, by

$$F(x) = f(x) + \min_{y \in V} g(x, y) \quad \forall x \in U,$$

$$\bar{F}(x, y) = f(x) + g(x, y) \quad \forall (x, y) \in U \times V.$$

**Lemma 3.1.** (1) The function $F : U \to \mathbb{R}$ is Lipschitz-continuous. Moreover, there exists a unique $x^* \in U$ such that $F(x^*) = \min_{x \in U} F(x)$.

(2) The function $\bar{F} \in C^2(U \times V)$ and is strictly convex. Moreover, there exists a unique $(\bar{x}, \bar{y}) \in U \times V$ such that $\bar{F}(\bar{x}, \bar{y}) = \min_{(x,y) \in U \times V} \bar{F}(x, y)$.

(3) We have $\min_{x \in U} F(x) = \min_{(x,y) \in U \times V} \bar{F}(x, y)$. Moreover, $(x^*, y_{x^*}) = (\bar{x}, \bar{y})$.

**Proof.** (1) Let $x', x'' \in U$. Since $\min_{y \in V} g(x'', y) = g(x'', y_{x''})$ by the assumption (a3), we have

$$\min_{y \in V} g(x', y) - \min_{y \in V} g(x'', y) \leq g(x', y_{x''}) - g(x'', y_{x''}) \leq K|x' - x''|,$$

where $K = \max_{(x,y) \in U \times V} |\nabla_y g(x, y)|$. Switching $x$ and $x'$ and noting that $f \in C^1(U)$, we see that $F : U \to \mathbb{R}$ is Lipschitz-continuous. Since $F$ is continuous on $U$ and $U$ is compact, there exists $x^* \in U$ such that $F(x^*) = \min_{x \in U} F(x)$. The uniqueness of $x^*$ follows from Part (3).

(2) These follow from the assumptions on $f$ and $g$, and the compactness of $U \times V$.

(3) Clearly, $\bar{F}(x) = \bar{F}(x, y_x) \geq \bar{F}(\bar{x}, \bar{y})$ for any $x \in U$ (cf. the assumption (a3)). Hence, $\min_{x \in U} F(x) \geq \min_{(x,y) \in U \times V} \bar{F}(x, y)$. On the other hand,

$$\min_{(x,y) \in U \times V} \bar{F}(x, y) = \bar{F}(\bar{x}, \bar{y}) \geq f(\bar{x}) + g(\bar{x}, y_{x^*}) = F(\bar{x}) \geq \min_{x \in U} F(x).$$

Thus, $\min_{x \in U} F(x) = \min_{(x,y) \in U \times V} \bar{F}(x, y)$. This also implies that $\bar{F}(x^*, y_{x^*}) = F(x^*) = \bar{F}(\bar{x}, \bar{y})$. Since the minimizer of $\bar{F}$ is unique, we have $(x^*, y_{x^*}) = (\bar{x}, \bar{y})$. □

**A min-min algorithm for finding $x^* = \arg\min_{x \in U} F(x)$.**

Step 0. Choose $x_0 \in U$. If $x_0 = x^*$ then stop. Otherwise, compute $y_0 = \arg\min_{y \in V} g(x_0, y)$. Set $k = 0$. 

12
Step 1. Compute
\[ \alpha_k = \text{argmin}_{\alpha \in A_k} \{ F(x_k - \alpha \nabla_x F(x_k, y_k), y_k) \}, \]
where \( A_k = \{ \alpha > 0 : x_k - \alpha \nabla_x F(x_k, y_k) \in U \} \), \( x_{k+1} = x_k - \alpha_k \nabla_x F(x_k, y_k) \).

Step 2. Compute \( y_{k+1} = \text{argmin}_{y \in \mathcal{V}} g(x_{k+1}, y) \).

Step 3. If \( x_{k+1} = x^* \) then stop. Otherwise, set \( k := k + 1 \) and repeat Steps 1–3.

**Theorem 3.2.** Assume \( x^* = \text{arg min}_{x \in \mathcal{U}} F(x) \in U \). Let \( x_0 \in U \) and \( y_0 = y_{x_0} \in V \). Assume
\[ W_0 := \{ (x, y) \in U \times V : F(x, y) \leq F(x_0, y_0) \} \subset U \times V. \]
Let \( \{ x_k \}_{k=1}^{\infty} \) be generated by the min-min algorithm. Then, \( x_k = x^* \) for some \( k \geq 0 \) or \( x_k \to x^* \).

**Proof.** Let us assume \( x_k \neq x^* \) for any \( k \geq 0 \) and show that \( x_k \to x^* \). Define for each \( k \geq 1 \) the set \( W_k \) the same as \( W_0 \) with \( (x_0, y_0) \) replaced by \( (x_k, y_k) \). We first show the following statement for each \( k \geq 0 \): there exists a unique \( \alpha_k \in A_k \) as defined in Step 1, the point \( (x_k, y_k) \) defined in the algorithm satisfies \( (x_k, y_k) \in \text{int}(W_k) \) and \( d^{(k)} := \nabla_x F(x_k, y_k) \neq 0 \), \( F(x_{k+1}, y_{k+1}) < F(x_k, y_k) \), and \( W_{k+1} \subseteq W_k \).

Consider \( k = 0 \). Since \( y_0 = y_{x_0} = \text{argmin}_{y \in \mathcal{V}} g(x_0, y) \in V \) (cf. the assumption (a3)), \( \nabla_y F(x_0, y_0) = \nabla_y g(x_0, y_0) = 0 \). Since \( x_0 \neq x^* \), and since by Lemma 3.1 \( (x^*, y_{x^*}) \in U \times V \) is the unique minimizer of \( F \) over \( U \times V \), we have \( d^{(0)} := \nabla_x F(x_0, y_0) \neq 0 \). It follows from Taylor’s expansion that
\[ F(x_0 - \alpha d^{(0)}, y_0) = F(x_0, y_0) - \alpha \| d^{(0)} \|^2 + O(\alpha^2) < F(x_0, y_0) \quad \text{if } 0 < \alpha \ll 1. \]

By the assumption that the closed set \( W_0 \subset U \times V \) and the strict convexity of \( F \), there exists a unique \( \alpha_0 \in A_0 \) such that \( F(x_0 - \alpha_0 d^{(0)}, y_0) \leq F(x_0 - \alpha d^{(0)}, y_0) \) for all \( \alpha \in A_0 \). Now \( x_1 = x_0 - \alpha_0 \nabla_y F(x_0, y_0) \in U \) and \( F(x_1, y_0) < F(x_0, y_0) \). By Step 2 of the algorithm and the assumption (a3), \( y_1 = y_{x_1} \in V \) and \( F(x_1, y_1) < F(x_1, y_0) < F(x_0, y_0) \). It then follows from the definition of \( W_0 \) that \( (x_1, y_1) \in \text{int}(W_0) \subset U \times V \). Clearly, \( W_1 \subseteq W_0 \). Thus, the statement is true for \( k = 0 \). Suppose the statement is true for \( k \geq 1 \). Using the above argument with \( (x_0, y_0) \) and \( W_0 \) replaced by \( (x_k, y_k) \) and \( W_k \), respectively, we verify that the statement is also true for \( k + 1 \). Therefore, the statement is true in general by induction.

We now prove \( x_k \to x^* \). Since \( \{ x_k \} \) is bounded, it suffices to show the following: if a subsequence of \( \{ x_k \} \), not relabeled, converges to some \( \hat{x} \in \mathcal{U} \), then \( \hat{x} = x^* \). First note that \( F(x_k, y_k) \to F \) for some \( F \in \mathbb{R} \), as \( \{ F(x_k, y_k) \} \) is decreasing and bounded. Now, passing to a further subsequence if necessary, we have \( (x_k, y_k) \to (\hat{x}, \hat{y}) \). By the above statement, \( (x_k, y_k) \in \text{int}(W_0) \) for all \( k \). Hence \( (\hat{x}, \hat{y}) \in W_0 \subset U \times V \). Therefore, it follows from the continuity of \( F \) that \( \hat{F} = F(\hat{x}, \hat{y}) \). Note for each \( k \) that \( \nabla_y F(x_k, y_k) = \nabla_y g(x_k, y_k) = 0 \). Consequently, \( \nabla_y \hat{F}(\hat{x}, \hat{y}) = 0 \). We shall show that \( \hat{d} := \nabla_x \hat{F}(\hat{x}, \hat{y}) = 0 \). This would imply that \( (\hat{x}, \hat{y}) \in U \times V \) is the unique minimizer of \( \hat{F} \) over \( U \times V \), and hence \( \hat{x} = x^* \) by Lemma 3.1 and \( x_k \to x^* \).

Assume \( \hat{d} \neq 0 \). Since \( (x_k, y_k) \in \{ (\hat{x}, \hat{y}) \} \) and \( d^{(k)} := \nabla_x F(x_k, y_k) \to \hat{d} \), it follows from the same argument used above that there exists \( \hat{\alpha} > 0 \) and an integer \( k_0 \geq 1 \) such that \( F(\hat{x} - \hat{\alpha} \hat{d}, \hat{y}) < F(\hat{x}, \hat{y}), (\hat{x} - \hat{\alpha} \hat{d}, \hat{y}) \in \text{int}(W_0) \), and \( (x_k - \hat{\alpha} d^{(k)}, y_k) \in \text{int}(W_0) \) if \( k \geq k_0 \). Now, since \( F(x_k, y_k) \) decreases and converges to \( \hat{F} = F(\hat{x}, \hat{y}) \) and \( y_{k+1} = y_{x_{k+1}} \) (cf. the assumption (a3) and Step 2 in the algorithm), we have by the definition of \( x_{k+1} \) (cf. Step 1 in the algorithm) that for all \( k \geq k_0 \)
\[ F(\hat{x}, \hat{y}) \leq F(x_{k+1}, y_{k+1}) \leq F(x_{k+1}, y_k) = F(x_k - \alpha_k d^{(k)}, y_k) \leq F(x_k - \hat{\alpha} d^{(k)}, y_k). \]
Taking $k \to \infty$, we get $\mathbf{F}(\hat{x}, \hat{y}) \leq \mathbf{F}(\hat{x} - \hat{a} \hat{d}, \hat{y}) < \mathbf{F}(\hat{x}, \hat{y})$, a contradiction. Thus, $\hat{d} = 0$.  

We remark that the proof of the convergence of the min-min algorithm relies on the fact that $\min_{x \in \Omega} F(x) = \min_{(x,y) \in \Omega \times \mathbb{V}} \mathbf{F}(x, y)$ and $(x^*, y_{x^*}) = (\hat{x}, \hat{y})$ as established in Lemma 3.1. Such structure is lost for a max-min algorithm and therefore the method of proof of Theorem 3.2 does not extend directly to the convergence of a max-min algorithm.

### 3.3 A radially symmetric system for the solvation of a single ion

We apply the variational implicit-solvent model (VISM) to the solvation of a single ion placed at the origin (i.e., $N = 1$ in Figure 1). The resulting system is simplified to be radially symmetric. Such a system is effectively one-dimensional for which we can obtain a very accurate solution for testing our algorithms.

We set $\Omega_- = \{ x \in \mathbb{R}^3 : |x| < R \}$, $\Omega_+ = \{ x \in \mathbb{R}^3 : R < |x| < A \}$, and $\Gamma = \{ x \in \mathbb{R}^3 : |x| = R \}$, where $A, R \in \mathbb{R}$ with $0 < R < A$, and denote $\chi_- = \chi_{(0,R)}$ and $\chi_+ = \chi_{(R,A)}$. The dielectric coefficient is $\varepsilon_R : [0, A] \to \mathbb{R}$ with $\varepsilon_R(r) = \varepsilon_-$ if $r < R$ and $\varepsilon_R(r) = \varepsilon_+$ if $r > R$. The LJ parameters for the single ion are denoted by $\varepsilon$, $\sigma$; cf. Figure 1 and (3.1). We assume $f : [0, A] \to \mathbb{R}$ is a smooth function, $g \in \mathbb{R}$, and $\mu > 0$. The electrostatic potential $\phi$ is assumed to be radially symmetric: $\hat{\phi}(r) = \phi(r)$ with $r = |x|$. The dielectric displacement $D$ is proportional to $\nabla_p(\phi(r)) = \phi'(r)(x/r)$. Thus, we assume $D(x) = p(r)(x/r)$ for some radially symmetric function $p = p(r)$. Since $|D(x)| = |p(r)|$ and

$$\nabla \cdot D(x) = \frac{2}{r} p(r) + p'(r) = \frac{1}{r^2} (p(r))',$$

we shall consider $p = p(r)$ instead of $D(x)$. We have $p = -\varepsilon_R \phi'$ if $D = -\varepsilon_\Gamma \nabla \phi$.

We denote $\omega(r) = r^2$ and define

$$H^1_\omega(0, A) = \{ \phi : (0, A) \to \mathbb{R} : \phi \text{ is weakly differentiable and } \int_0^A (\phi'^2 + \phi'^2) r^2 dr < \infty \},$$

(3.5)

$$X_g = \{ \phi \in H^1_\omega(0, A) : \phi(A) = g \};$$

(3.6)

$$Y = \left\{ p : (0, A) \to \mathbb{R} : p \text{ is weakly differentiable and } \int_0^A [(r^2 p)^2 + (r^2 p')^2] \frac{1}{r^2} dr < \infty \right\},$$

(3.7)

$$Y_f = \left\{ p \in Y : \frac{2}{r} p + p' = f \text{ in } (0, R) \right\}.$$  

(3.8)

Both $H^1_\omega(0, A)$ and $Y$ are Hilbert spaces with their inner products and norms given respectively by

$$\langle \phi, \psi \rangle_\omega = \int_0^A (\phi(\psi + \phi' \psi')) r^2 dr \quad \text{and} \quad \| \phi \|_\omega = \sqrt{\langle \phi, \phi \rangle_\omega},$$

$$\langle p, q \rangle_Y = \int_0^A [(r^2 p)(r^2 q) + (r^2 p')(r^2 q')] \frac{1}{r^2} dr \quad \text{and} \quad \| p \|_Y = \sqrt{\langle p, p \rangle_Y},$$

If $\phi \in H^1_\omega(0, A)$ and $0 < \delta < A$, then $\phi \in H^1(\delta, A)$ and hence $\phi$ is absolutely continuous on $[\delta, A]$, and the trace $\phi(A)$ is well defined. One verifies that $Y = H^1_\omega(0, A) \cap L^2(0, A)$. If $p \in Y,$
then \( p \in H^1(\delta, A) \) for any \( \delta \in (0, A) \), and hence the trace \( p(A) \) is well defined. The equation in defining \( Y_f \) is \( (r^2 p(r))' = r^2 f(r) \) for \( 0 < r < R \), same as the constraint \( \nabla \cdot D = f \) in \( \Omega_- \) in the cartesian coordinates for \( D(r) = p(r) (\varepsilon/r) \).

To compare the min-min and max-min algorithms, we now express the VISM solvation free energy with the classical PB and the penalized LTPB electrostatic energies in the radially symmetric setting. The nonpolar part of the solvation free energy (i.e., the first three terms of \( F[\Gamma] \) defined in (3.1)) \( F_0 : (0, A) \to \mathbb{R} \) and its boundary variation \( \delta_R F_0 : (0, A) \to \mathbb{R} \) are

\[
F_0(R) = \frac{4\pi}{3} P_0 R^3 + 4\pi \gamma_0 R^2 - 8\pi \gamma_0 \tau R + 16\pi \rho_w \varepsilon \left( \frac{\sigma_{12}^2}{9R^9} - \frac{\sigma_{6}^2}{3R^3} \right),
\]

(3.9)

\[
\delta_R F_0(R) = P_0 + 2\gamma_0 \frac{R}{R^2} - 2\gamma_0 \tau R^2 + 4\rho_w \varepsilon \left( \frac{\sigma_{12}^2}{9R^9} - \frac{\sigma_{6}^2}{3R^3} \right).
\]

(3.10)

Note that the boundary variation \( \delta_R F_0 \) differs from the derivative \( F'_0(R) \) by the factor \( 4\pi R^2 \); cf. [6].

**Case 1. A continuum charge density.** The VISM-PB free-energy functional \( F : (0, A) \to \mathbb{R} \) with \( I_R : X_g \to \mathbb{R} \) and the boundary variation \( \delta_R F : (0, A) \to \mathbb{R} \) are now given by (cf. (1.4) and (3.1)–(3.3))

\[
F(R) = F_0(R) + \max_{\phi \in X_g} I_R[\phi],
\]

(3.11)

\[
I_R[\phi] = 4\pi \int_0^A \left[ -\frac{\varepsilon_R}{2} |\phi'|^2 + f \phi - \chi B(\phi) \right] r^2 dr,
\]

(3.12)

\[
\delta_R F(R) = \delta_R F_0(R) + \frac{1}{2} \left( \frac{1}{\varepsilon_-} - \frac{1}{\varepsilon_+} \right) [\varepsilon_R \phi'_R(R)]^2 + B (\phi_R(R)),
\]

(3.13)

where \( \phi_R = \arg\min_{\phi \in X_g} I_R[\phi] \); cf. Theorem 3.3. The penalized VISM-LTPB free-energy functional \( F_\mu : (0, A) \to \mathbb{R} \) with \( J_{R,\mu} : Y \to \mathbb{R} \) and its boundary variation \( \delta_R F_\mu : (0, A) \to \mathbb{R} \) are given by (cf. (3.1), (3.4), (3.9), and part (1) of Theorem 3.1)

\[
F_\mu(R) = F_0(R) + \min_{p \in Y} J_{R,\mu}[p],
\]

(3.14)

\[
J_{R,\mu}[p] = 4\pi \int_0^A \left[ \frac{1}{2\varepsilon_R} p^2 + \chi B^* \left( f - \left( \frac{2}{r} p + p' \right) \right) + \frac{\chi}{2\mu} \left( f - \left( \frac{2}{r} p + p' \right) \right)^2 \right] r^2 dr
\]

\[
+ 4\pi \rho_p(A) A^2,
\]

(3.15)

\[
\delta_R F_\mu(R) = \delta_R F_0(R) + \frac{1}{2} \left( \frac{1}{\varepsilon_-} - \frac{1}{\varepsilon_+} \right) [p_{R,\mu}(R)]^2
\]

\[
+ B \left( B^* \left( f(R) - p'_{R,\mu}(R) - \frac{2}{R} p_{R,\mu}(R) \right) \right)
\]

\[
- \frac{1}{2\mu} \left( f(R) - p'_{R,\mu}(R) - \frac{2}{R} p_{R,\mu}(R) \right)^2,
\]

(3.16)

(3.17)

where \( p_{R,\mu} = \arg\min_{p \in Y} J_{R,\mu}[p] \); cf. Theorem 3.3.
Case 2. A single point charge. With the point charge $Q$ at the origin, the VISM-PB free-energy functional $\hat{F} : (0, A) \to \mathbb{R}$ with $\hat{I}_R : X_g \to \mathbb{R}$ and the boundary variation $\delta_R \hat{F} : (0, A) \to \mathbb{R}$ are given by (cf. (3.1), (3.2), (2.7), and (3.3))

$$
F(R) = F_0(R) + \max_{\phi \in X_g} \hat{I}_R[\phi],
$$

$$
\hat{I}_R[\phi] = 4\pi \int_0^A \left[ -\frac{\chi_\varepsilon}{2} \left( \phi' + \frac{Q}{4\pi \varepsilon \varepsilon_- r^2} \right)^2 - \frac{\chi_+}{2} \left( \phi' + \frac{Q}{4\pi \varepsilon_+ r^2} \right)^2 - \chi_+ B(\phi) \right] r^2 dr + \frac{Q^2}{8\pi} \left[ \left( \frac{1}{\varepsilon_-} - \frac{1}{\varepsilon_+} \right) \frac{1}{R} - \frac{1}{\varepsilon_+ A} \right],
$$

$$
\delta_R \hat{F}(R) = \delta_R F_0(R) + \frac{1}{2} \left[ \varepsilon_+ [\varepsilon_- B_+(\phi')]^2 + B(\phi_R(R)) \right],
$$

where $\phi_R = \arg\max_{\phi \in X_g} \hat{I}_R[\phi]$; cf. Theorem 3.3. The penalized VISM-LTPB energy functional $\hat{F} : (0, A) \to \mathbb{R}$ with $\hat{J}_{R,\mu} : Y \to \mathbb{R}$ and the boundary variation $\delta_R \hat{F}_\mu : (0, A) \to \mathbb{R}$ are now given by (cf. (3.1), (3.4), (2.7), and part (2) of Theorem 3.1)

$$
\hat{F}_\mu(R) = F_0(R) + \min_{p \in Y} \hat{J}_{R,\mu}[p],
$$

$$
\hat{J}_{R,\mu}[p] = 4\pi \int_0^A \left\{ \frac{1}{2\varepsilon_R} p^2 + \frac{\chi_-}{2\mu} \left( \frac{2}{r} p + p' \right)^2 + \chi_+ \left[ B^* \left( -\frac{2}{r} p - p' \right) + \hat{\phi}_{Y,\infty} \left( \frac{2}{r} p + p' \right) \right] \right\} r^2 dr + \frac{Q^2}{8\pi} \left[ \left( \frac{1}{\varepsilon_-} - \frac{1}{\varepsilon_+} \right) \frac{1}{R} - \frac{1}{\varepsilon_+ A} \right],
$$

$$
\delta_R \hat{F}_\mu(R) = \delta_R F_0(R) + \frac{1}{2} \left( \frac{1}{\varepsilon_-} - \frac{1}{\varepsilon_+} \right) \left( p_{R,\mu}(R) + \frac{Q}{4\pi R^2} \right)^2
$$

$$
+ B \left( B^{*'} \left( \frac{2}{R} p_{R,\mu}(R+) + \frac{Q}{4\pi R^2} \right) \right) - \frac{1}{2\mu} \left( p_{R,\mu}(R-) + \frac{2}{R} p_{R,\mu}(R-) \right)^2,
$$

where $p_{R,\mu} = \arg\min_{p \in Y} \hat{J}_{R,\mu}[p]$; cf. Theorem 3.3.

We note that, while the radial symmetry of functions simplifies our models and computations, the analysis in section 2 does not directly apply here due to possible singularities at the origin. Thus, we present here a similar analysis for the radially symmetric system, but only for the case of a continuum charge density, as the case of point charges is similar. In Appendix, we also provide a new and direct derivation of the boundary force in the one-dimensional setting. Let us define $I_{R,\mu} : X_g \to \mathbb{R} \cup \{-\infty\}$ and $J_R : Y_f \to \mathbb{R} \cup \{\infty\}$, respectively, by

$$
I_{R,\mu}[\phi] = 4\pi \int_0^A \left[ -\frac{\varepsilon_R}{2} |\phi'|^2 + f \phi - \chi_+ B(\phi) - \frac{\chi_-}{2} \phi^2 \right] r^2 dr,
$$

$$
J_R[p] = 4\pi \int_0^A \left[ \frac{1}{2\varepsilon_R} p^2 + \chi_+ B^* \left( f - \frac{2}{r} p + p' \right) \right] r^2 dr + 4\pi gp(A) A^2.
$$
Lemma 3.2. Particularly the behavior near $r < 0$

Theorem 3.3. (1) Denote $I_{R,0} = I_R$. For each $\mu \geq 0$, there exists a unique $\phi_{R,\mu} \in X_g$ such that $I_{R,\mu}[\phi_{R,\mu}] = \max_{\phi \in X_g} I_{R,\mu}[\phi]$. Moreover, $\phi_{R,\mu} \in X_g$ is the unique solution to

$$
\frac{\varepsilon_-}{r^2} (r^2 \phi')' - \mu \phi = -f \quad \text{in } (0,R) \quad \text{and} \quad \frac{\varepsilon_+}{r^2} (r^2 \phi')' - B'(\phi) = -f \quad \text{in } (R,A),
$$

and $\varepsilon_- \phi'(R-) = \varepsilon_+ \phi'(R+)$ and $\phi(A) = g$.

(2) Duality. We have $I_R[\phi] \leq J_R[p]$ for any $\phi \in X_g$ and $p \in Y_f$, and $I_{R,\mu}[\phi] \leq J_{R,\mu}[p]$ for any $\mu > 0$, $\phi \in X_g$, and $p \in Y$. Moreover, $p_R := -\varepsilon_R \phi'_R \in Y_f$ and $p_{R,\mu} := -\varepsilon_R \phi'_{R,\mu} \in Y$ ($\mu > 0$) are the unique minimizers of $J_R$ over $Y_f$ and $J_{R,\mu}$ over $Y$, respectively.

(3) Convergence. We have $\|\phi_{R,\mu} - \phi_R\|_\omega \to 0$, $\max_{\phi \in X_g} I_{R,\mu}[\phi] \to \max_{\phi \in X_g} I_R[\phi]$, $\|p_{R,\mu} - p_R\|_Y \to 0$, and $\min_{p \in Y} J_{R,\mu}[p] \to \min_{p \in Y} J_R[p]$ as $\mu \to 0$.

To prove Theorem 3.3, we need the following lemma that summarizes some properties, particularly the behavior near $r = 0$, of the functions in $H^1_+(0,A)$ (cf. (3.5)) and $Y$ (cf. (3.7)):

Lemma 3.2. Let $\phi \in H^1_+(0,A)$ and $p \in Y$. Define $u(r) = r^2 p(r)$ and $v(r) = r^2 \phi(r)p(r)$ for $0 < r \leq A$. Then, $\sup_{0 < r < A} \sqrt{r} |\phi(r)| < \infty$, $u \in H^1(0,A)$ and $u(r) = o(r^{3/2})$ as $r \to 0$, and $v \in W^{1,1}(0,A)$ and $v(r) = o(r)$ as $r \to 0$.

Proof. Note for any $\delta \in (0,A)$ that $\phi \in H^1(\delta,A)$ and hence $\phi$ is absolutely continuous on $[\delta,A]$. Hence,

$$
\phi(r)^2 = \left[ \phi(A) - \int_r^A \phi'(s) \, ds \right]^2
\leq 2 \phi(A)^2 + 2 \left( \int_r^A \phi'(s) \, ds \right)^2
\leq 2 \phi(A)^2 + 2 \left( \int_r^A s^2 \phi'(s)^2 \, ds \right) \left( \int_r^A s^{-2} \, ds \right)
= 2 \phi(A)^2 + 2 \left( \int_r^A s^2 \phi'(s)^2 \, ds \right) \left( \frac{1}{r} - \frac{1}{A} \right)
\leq 2 \phi(A)^2 + \frac{2}{r} \|\phi\|_\omega^2 \quad \forall r \in (0,A).
$$

Consequently, $r \phi(r)^2 \leq 2 A \phi(A)^2 + 2 \|\phi\|_{H^1_+(0,A)}^2$ if $r \in (0,A)$, and hence $\sup_{0 < r < A} \sqrt{r} |\phi(r)| < \infty$.

Since $p \in Y$, we can directly verify that $u \in H^1(0,A)$, and hence $u$ is absolutely continuous on $[0,A]$. We must have $u(0) := \lim_{r \to 0} u(r) = 0$, since

$$
\int_0^A u(r)^2 / r^2 \, dr = \int_0^A r^2 p(r)^2 \, dr < \infty.
$$

Consequently,

$$
u(r)^2 = \left( \int_0^r u'(s) \, ds \right)^2 \leq \left( \int_0^r s^2 \, ds \right) \left( \int_0^r \frac{u'(s)^2}{s^2} \, ds \right) = \frac{1}{3} r^3 o(1) \quad \text{as } r \to 0,
$$

and hence $u(r) = o(r^{3/2})$ as $r \to 0$. 17
Since \( v(r) = r^2\phi(r)p(r) \) \((0 < r < A)\), we have \( \|v\|_{L^1(0,A)} \leq \|\phi\|_\infty p \|_Y < \infty \). Consequently,

\[
\int_0^A |v'(r)|dr = \int_0^A |\phi'(r)r^2p(r) + \phi(r)(r^2p(r))'|dr
\leq \int_0^A |r\phi'(r)rp(r)|dr + \int_0^A \left| r\phi(r) \left[ \frac{r^2p(r)'}{r} \right] \right| dr
\leq \left( \int_0^A r^2\phi'(r)^2dr \right)^{1/2} \left( \int_0^A r^2p(r)^2dr \right)^{1/2}
+ \left( \int_0^A r^2\phi(r)^2dr \right)^{1/2} \left( \int_0^A (r^2p(r))' \left[ \frac{1}{r^2} \right] \right)^{1/2}
\leq 2\|\phi\|_\infty p \|_Y < \infty.
\]

Hence, \( v \in W^{1,1}(0,A) \), it is absolutely continuous, and \( v(r) = \sqrt{r}\phi(r)u(r)/\sqrt{r} = o(r) \) as \( r \to 0 \).

**Proof of Theorem 3.3.** (1) The proof of this part is standard; cf. [19, 20, 23].

(2) Let \( \mu > 0, \phi \in X_g \), and \( p \in Y \). Since \( \phi(A) = g \) and \( \lim_{r\to0^+} r^2\phi(r)p(r) = 0 \) by Lemma 3.2,

\[
\int_0^A p\phi'r^2dr = -\int_0^A (r^2p)\phi'dr + gp(A)A^2 = -\int_0^A \left( \frac{2}{r}p + p' \right) \phi r^2dr + gp(A)A^2.
\]

Consequently, by the fact that the Legendre transform of \( s \mapsto (\mu/2)s^2 \) is \( \xi \mapsto \xi^2/(2\mu) \), we obtain

\[
I_{R,\mu}[\phi] \leq I_{R,\mu}[\phi] + 4\pi \int_0^A \frac{1}{2\varepsilon_R} |p + \varepsilon_R\phi|^2 r^2dr
= 4\pi \int_0^A \left( f\phi - \chi_+B(\phi) - \frac{\chi_-\mu}{2} \phi^2 + \frac{1}{2\varepsilon_R} p^2 + p\phi' \right) r^2dr
= 4\pi \int_0^A \left\{ \frac{1}{2\varepsilon_R} p^2 + \chi_+ \left[ \left( f - \left( \frac{2}{r}p + p' \right) \right) \phi - B(\phi) \right]
+ \chi_- \left[ \left( f - \left( \frac{2}{r}p + p' \right) \right) \phi - \frac{\mu}{2} \phi^2 \right] \right\} r^2dr + 4\pi gp(A)A^2
\leq 4\pi \int_0^A \left[ \frac{1}{2\varepsilon_R} p^2 + \chi_+B^* \left( f - \left( \frac{2}{r}p + p' \right) \right) + \chi_-\frac{\mu}{2} \left( f - \left( \frac{2}{r}p + p' \right) \right) \right] r^2dr
+ 4\pi gp(A)A^2
= J_{R,\mu}[p].
\] (3.26)

The inequality \( I_R[\phi] \leq J_{R}[p] \) for any \( \phi \in X_g \) and \( p \in Y_f \) can be proved similarly.

By part (1), \( p_{R,\mu} = -\varepsilon_R\phi_{R,\mu}' \) satisfies

\[
(r^2p_{R,\mu})' = (f - \mu\phi_{R,\mu})r^2 \text{ in } (0, R) \quad \text{and} \quad (r^2p_{R,\mu})' = (f - B'(\phi_{R,\mu}))r^2 \text{ in } (R, A).
\] (3.27)

These and the fact that \( \phi_{R,\mu} \in X_g \) imply that \( p_{R,\mu} \in Y \). Moreover, the first inequality in (3.26) becomes an equality with \( \phi_{R,\mu} \) and \( p_{R,\mu} = -\varepsilon_R\phi_{R,\mu}' \) replacing \( \phi \) and \( p \), respectively. The
second inequality in (3.26) also becomes an equality by (3.27) and the definition of the Legendre transform. Thus, by the convexity of \(J_{R,\mu}\), \(p_{R,\mu}\) is the unique minimizer of \(J_{R,\mu}\) over \(Y\). Similarly, \(p_R\) is the unique minimizer of \(J_\mu\) over \(Y_f\).

(3) By the same argument used in proving part (2) of Theorem 2.3, we have \(\|\phi_{R,\mu} - \phi_R\|_\omega \to 0\) and \(\max_{\phi \in X_g} I_{R,\mu}[\phi] \to \max_{\phi \in X_g} I_R[\phi]\) as \(\mu \to 0\). These and part (2) imply \(\|p_{R,\mu} - p_R\|_Y \to 0\) and \(\min_{p \in Y} J_{R,\mu}[\phi] \to \min_{p \in Y_f} J_R[p]\) as \(\mu \to 0\).

3.4 Numerical results

In this section, we present numerical results of the solvation of a spherical molecule such as a single ion. We first demonstrate that both the min-min algorithm for the VISM with the LTPB formulation of electrostatics and the max-min algorithm for the VISM with the PB formulation of electrostatics can achieve the same accuracy. Note that the two formulations are equivalent (cf. Theorem 2.1, Theorem 2.2, and Theorem 3.3). But the penalty method used to approximate the constraint by Gauss’ law lead to approximation errors. Such errors converge to 0 as the penalty parameter \(\mu \to 0\) (cf. Theorem 2.3 and Theorem 3.3). We then test and compare the two algorithms in terms of a small number of iteration steps that are often designed for large-scale molecular simulations. We finally show that the VISM with the LTPB electrostatics implemented with our min-min algorithm can predict accurately the solvation free energy for a single ion. All the model parameters we use for numerical simulations are taken from [40] and are summarized in Table 1.

3.4.1 Comparison of the min-min and max-min algorithms with given tolerance to reach

We first consider a continuum charge density (cf. Case 1 in section 3.3) and compare the min-min and max-min algorithms with a given tolerance. We set the continuum charge density to be \(f(r) = (1000/\sqrt{8\pi^3})e^{-50r^2}\) and also set \(B(s) = s^2/2\) and \(g = 0\). We minimize the total solvation free energy functionals \(F_\mu = F_\mu(R)\) defined in (3.14) and \(F = F(R)\) defined in (3.11) with minimizing the corresponding LTPB electrostatic energy functional \(J_{R,\mu} = J_{R,\mu}[p]\) defined in (3.15) and maximizing the electrostatic energy functional \(I_R = I_R[\phi]\) defined in (3.12), respectively, to compare the minimized total free energy and the optimal radius. Three
values of the penalty parameter $\mu$ and three different number $N$ of grid points are tested. The conjugate gradient method is used for minimizing the electrostatic energy functionals $J_{R,\mu}$ and $-I_R$ (equivalently maximizing $I_R$). The gradient descent method is used for minimizing the total free-energy functionals $F_\mu = F_\mu(R)$ and $F(R)$ to get the minimum value of free energy and also the minimizing radius. The initial guess of the radius is $R_0 = 2.5$. The tolerance for the $L^2$-norm of the gradient is chosen to be $10^{-5}$ and maximum iteration steps is set as 50,000. The iteration of the conjugate gradient method is terminated if the tolerance or the maximum number of steps is reached. Our results are shown in Table 2. We observe that as $\mu > 0$ gets smaller the error between the min-min and max-min simulations also gets smaller. This is expected by the duality of two formulations and the convergence of our penalty method; cf. Theorem 3.3. Moreover, a moderate value of $\mu$ leads to the best performance of the min-min algorithm in terms of accuracy and efficiency.

We now consider a single point charge $Q = 1$ placed at the origin, and set $B(s) = \cosh(s) - 1$. We use the nonlinear conjugate gradient method for the first minimization or maximization, and then the gradient descent method for the second minimization for updating the radius $R$ with initial guess $R_0 = 2$. In the nonlinear conjugate gradient method, the tolerance for the $L^2$-norm of the gradient is chosen as $10^{-5}$ and maximum iteration steps is set as 100,000. We test on three different values of the penalty parameter $\mu$ and also three different numbers of grid point. Our results are shown in Table 3. We again observe that as $\mu > 0$ gets smaller the error between the min-min and max-min simulations also gets smaller, verifying the duality and the convergence of our penalty method; cf. Theorem 3.3. It is also clear that a moderate value of $\mu$ again leads to the best performance of the min-min algorithm in terms of accuracy and efficiency.
Table 3: Results of min-min and max-min simulations for a single point charge $Q = 1$ placed at the origin.

3.4.2 Comparison of the min-min and max-min algorithms with a few steps of iterations

We set $A = 4$, $B(s) = s^2/2$, $f(r) = (1000/\sqrt{8\pi^3})e^{-50r^2}$, and $g = 0$. All the units are the same as in [40]; cf. Table 1. We first minimize the total free energy $F(R)$ with the initial guess $R_0 = 2.5$ and a very fine grid and many iteration steps to get an “exact” minimum value $F_{\text{min}} = 1480.1331$ and an “exact” optimal radius $R_{\text{min}} = 2.7960$. We then apply the min-min algorithm to minimize the penalized VISM-LTPB functional and apply the max-min algorithm to minimize the VISM-PB functional. The gradient descent method is used to minimize the total energy with initial guess $R_0 = 2.5$. The conjugate gradient method with not so many iteration steps is used to minimize the LTPB energy and maximize the PB energy. In Table 4, we show our numerical results. We observe that in general the min-min algorithm performs much better than the max-min algorithm with a small value of $\mu$. For $2\mu = 10^{-3}$, the min-min algorithm does not converge due to the large penalty coefficient and small number of iteration steps.

We now compare the min-min and max-min algorithms for a single point charge. We set the charge at the origin to be $Q = 1$ and consider $B(s) = \cosh(s) - 1$. Other parameters are the same as for the case of a continuum charge density. We use the gradient descent iteration to minimize the total free energy $\tilde{F}_\mu(R)$ with the initial guess $R_0 = 2$, and use the nonlinear conjugate gradient method to maximize $\tilde{I}_{R_k}$ and minimize $\tilde{J}_{R_k,\mu}$, respectively. The “exact” minimum value $\tilde{F}_{\text{min}}$ and the “exact” minimizer $\tilde{R}_{\text{min}}$ are found by a very fine grid and many iteration steps to be $\tilde{F}_{\text{min}} = -89.6208$ and $\tilde{R}_{\text{min}} = 2.7997$. Table 5 shows our numerical results. We observe that in general the min-min algorithm performs much better than the max-min algorithm with a small value of $\mu$. For $2\mu = 10^{-5}$, the min-min and max-min algorithms perform compatibly in terms of the accuracy.
3.4.3 Prediction of the solvation free energy for single ions

We apply our min-min algorithm to minimize the penalized total VISM-LTPB free energy for the solvation of single ions $K^+$, $Na^+$, $Cl^-$ and $F^-$. For comparison, we also minimized the VISM-PB free energy for comparison. Here, the function $B$ is the hyperbolic cosine function, and all parameters are taken from [40] and are listed in Table 1. We set $2\mu = 10^{-3}$. The dielectric boundaries of the anion $Cl^-$ or $F^-$ are obtained by shifting the VISM equilibrium surface by $\xi = 1\text{Å}$, which is the length of the water OH bond [40]. In Table 6, we present our numerical
results with comparison with the VISM-CFA and VISM-PB computational results, and also with the experimental results. The CFA, the Coulomb-field approximation, is an approximation of the electrostatics with a dielectric boundary; cf. [39]. We see from Table 6 that our numerical results fit well with the experimental data, and for some cases, are better than those of the VISM-PB calculations. It is observed that the free energy predicted by VISM-LTPB is always larger in magnitude than that by VISM-PB. This is due to the extra penalty term in the penalty method that implements VISM-LTPB formulation.

Table 6: The solvation free energy (in $k_B T$) for each of the single ions $K^+$, $Na^+$, $Cl^-$ and $F^-$ modeled as a single point charge computed with the VISM-LTPB model. The computational results based on the VISM-CFA and VISM-PB models and the experimental results are also shown for comparison [29, 40].

4 Conclusions

We constructed the Legendre-transformed Poisson–Boltzmann (LTPB) electrostatic energy functional of dielectric displacements with application to variational solvation of charged molecules that are characterized by the dielectric boundary separating such solute molecules from the solvent. The solvation free energy in the variational solvation model includes the surface energy, electrostatic energy, and other energy terms. The convexity of the LTPB energy functional makes it consistent with the minimization of the total solvation free-energy functional.

We proved the duality between the convex LTPB functional and the classical concave Poisson–Boltzmann (PB) electrostatic energy functional. With a fixed dielectric boundary, we approximated our LTPB functional of the dielectric displacements constrained by Gauss’ law on the solute region by penalized LTPB functionals, removing the constraint. The convergence of this penalty method was shown. Finally, we designed a min-min method for minimizing the solvation free-energy functional of all dielectric boundaries: In each iteration step of relaxing the dielectric boundary, we minimize iteratively the LTPB electrostatic energy. The convergence of the min-min algorithm was proved. Numerical tests on the solvation of single ions demonstrated the efficiency and accuracy of our method, and for many cases, with suitably chosen penalty parameters and number of iteration steps, the LTPB formulation was more stable than the classical PB formulation.

We now discuss some possible issues and point out possible improvements for future studies. First, the explicit formula of the Legendre transform $B^* = B^*(\xi)$ of a given convex function $B = B(s)$ is generally not available. One can, however, generate a table of values $B^*(\xi)$ for selected values of $\xi \in [\xi_{\text{min}}, \xi_{\text{max}}]$, where the numbers $\xi_{\text{min}}$ and $\xi_{\text{max}}$ can be estimated from an underlying system. Note that the function $B = B(s)$ in the generalized PB theory with
ionic size effect is only implicitly defined [18, 21, 41]. One can, however, solve a system of nonlinear algebraic equations to obtain $B(s)$ for many selected $s$-values and then calculate $B^*(\xi)$ to generate a table.

Second, while our initial numerical tests have indicated that the LTPB formulation is better than the classical PB formulation, the constraint of the dielectric displacements slowed down the computations. Therefore, there is a need to construct a more efficient LTPB formulation for modeling the electrostatics in molecular solvation.

Third, for large systems of molecular solvation, the level-set method can be used to numerically relax the solvation free-energy functional with the LTPB formulation for the electrostatic energy [40]. It will also be interesting to use the level-set method to minimize the total solvation free energy of dielectric boundaries and compare the min-min and max-min algorithms, and hence compare the LTPB and PB formulations.

Finally, our convergence analysis of the min-min algorithm points out a new scheme of minimizing a free-energy functional of two variables with one depending on the other. One can view the free-energy functional as a two-variable functional and minimize it with respect to the two variables; cf. Lemma 3.1. In application to solvation, we can minimize the solvation free energy with respect to both the dielectric boundary $\Gamma$ and the dielectric displacement $D$.

**Appendix**

We derive the formula of the dielectric boundary force as negative energy variation for a model problem. Let $\varepsilon_-, \varepsilon_+ \in (0, \infty)$ with $\varepsilon_- \neq \varepsilon_+$. For any $\gamma \in I := (0, 1)$, we define $\varepsilon_\gamma : [0, 1] \to \mathbb{R}$ by $\varepsilon_\gamma(x) = \varepsilon_-$ if $x < \gamma$ and $\varepsilon_\gamma(x) = \varepsilon_+$ if $x > \gamma$. Let $f : [0, 1] \to \mathbb{R}$ be a smooth function. Define $E_\gamma : H^1_0(I) \to \mathbb{R}$ by

$$E_\gamma[\phi] = \int_0^1 \left( \frac{\varepsilon_\gamma}{2} \phi'^2 - f\phi \right) \, dx \quad \forall \phi \in H^1_0(I).$$

Let $\phi_\gamma \in H^1_0(I)$ be the unique minimizer of $E_\gamma$ over $H^1_0(I)$ and denote $e(\gamma) := E_\gamma[\phi_\gamma] = \min_{\phi \in H^1_0(I)} E_\gamma[\phi]$. The minimizer $\phi_\gamma$ is the unique function in $H^1_0(I)$ such that

$$\int_0^1 (\varepsilon_\gamma \phi_\gamma' \eta' - f \eta) \, dx = 0 \quad \forall \eta \in H^1_0(I). \tag{A.1}$$

Equivalently, $\phi_\gamma \in H^1_0(I)$ is the unique function satisfying $\phi_\gamma|_{\Omega_\pm} \in C^2(\mathcal{T}_\pm)$ and

$$-\varepsilon_\pm \phi''_\gamma = f \quad \text{in } I_\pm \quad \text{and} \quad [\phi_\gamma]_\gamma = [\varepsilon_\gamma \phi'_\gamma]_\gamma = 0, \tag{A.2}$$

where $I_- = (0, \gamma)$ and $I_+ = (\gamma, 1)$, and $[u]_\gamma = u(\gamma+) - u(\gamma-)$ for a given function $u$.

The boundary force is defined as $-e'(\gamma)$ if the derivative exists. Formulas for such forces for more general problems in multi-dimensions and non-linear Euler–Lagrange equations have been obtained in [20, 23]. Here, we give a totally different, direct, and self-closed derivation of such a force.

**Proposition A.1.** We have

$$e'(\gamma) = \frac{1}{2} \left( \frac{1}{\varepsilon_+} - \frac{1}{\varepsilon_-} \right) \left[ \varepsilon_\gamma \phi'_\gamma(\gamma) \right]^2,$$

where $\varepsilon_\gamma \phi'_\gamma(\gamma-) = \varepsilon_- \phi'_\gamma(\gamma-) = \varepsilon_+ \phi'_\gamma(\gamma+)$. 

24
Proof. We first establish some bounds for $\phi_{\gamma}$ and $\delta \phi_{\gamma} := \phi_{\gamma + \delta \gamma} - \phi_{\gamma}$ ($\delta \gamma \in \mathbb{R}$ and $0 < \gamma + \delta \gamma < 1$). Setting $\eta = \phi_{\gamma}$ in (A.1), we have by Poincaré’s inequality that $\|\phi_{\gamma}\|_{H^1_0(I)} \leq C$ for all $\gamma \in I$, where $C > 0$ is a constant independent of $\gamma \in I$. Since $\phi_{\gamma}(0) = 0$, we have $\phi_{\gamma}(x) = \int_0^x \phi'_{\gamma}(t) dt$ ($x \in I$). Hence, $\|\phi_{\gamma}\|_{L^\infty(I)} \leq C$ for all $\gamma \in I$.

Let $0 < \gamma_1 < \gamma < \gamma_2 < 1$. By (A.2) and the fact that $\phi_{\gamma}(1) = 0$, we have

$$-\varepsilon_+ \phi'_{\gamma}(y) + \varepsilon_+ \phi'_{\gamma}(\gamma+) = \int_\gamma^y f(t) \, dt \quad \forall y \in (\gamma, 1),$$

$$\varepsilon_+ \phi_{\gamma}(x) + \varepsilon_+ \phi'_{\gamma}(\gamma+)(1-x) = \int_x^1 \int_\gamma^y f(t) \, dt \, dy \quad \forall x \in (\gamma, 1).$$

These and the uniform bound on $\|\phi_{\gamma}\|_{L^\infty(I)}$ imply that $|\phi'_{\gamma}(\gamma+)| \leq C(\gamma_1, \gamma_2)$, and hence $|\phi'_{\gamma}(y)| \leq C(\gamma_1, \gamma_2)$ for all $y \in [\gamma, \gamma_2]$, where $C(\gamma_1, \gamma_2) > 0$ is a generic constant independent of $\gamma \in [\gamma_1, \gamma_2]$. Similarly, $|\phi'_{\gamma}(y)| \leq C(\gamma_1, \gamma_2)$ for all $y \in [\gamma_1, \gamma]$. Thus, $\|\phi_{\gamma}\|_{W^{1,\infty}([\gamma_1, \gamma_2])} \leq C(\gamma_1, \gamma_2)$ for all $\gamma \in [\gamma_1, \gamma_2]$.

Let $\delta \gamma \in \mathbb{R}$ be such that $0 < \gamma_1 < \gamma - |\delta \gamma| < \gamma + |\delta \gamma| < \gamma_2 < 1$. We shall assume that $\delta \gamma > 0$ as the case $\delta \gamma < 0$ is similar. Setting $\eta = \delta \phi_{\gamma} = \phi_{\gamma + \delta \gamma} - \phi_{\gamma}$ in (A.1) for $\phi_{\gamma}$ and in (A.1) with $\phi_{\gamma + \delta \gamma}$ replacing $\phi_{\gamma}$, respectively, and subtracting one from the other, we obtain

$$\int_0^1 \left[\varepsilon_{\gamma + \delta \gamma}(\delta \phi_{\gamma})' + (\varepsilon_{\gamma + \delta \gamma} - \varepsilon_{\gamma})\phi'_{\gamma}\right] (\delta \phi_{\gamma})' \, dx = 0.$$ 

This, together with the bound $\|\phi_{\gamma}\|_{W^{1,\infty}([\gamma_1, \gamma_2])} \leq C(\gamma_1, \gamma_2)$, implies that

$$\int_0^1 \varepsilon_{\gamma + \delta \gamma}(\delta \phi_{\gamma})^2 \, dx = \int_0^1 (\varepsilon_{\gamma} - \varepsilon_{\gamma + \delta \gamma})\phi'_{\gamma}(\delta \phi_{\gamma})' \, dx$$

$$= (\varepsilon_+ - \varepsilon_-) \int_\gamma^{\gamma + \delta \gamma} \phi'_{\gamma}(\delta \phi_{\gamma})' \, dx \leq C(\gamma_1, \gamma_2)\sqrt{\delta \gamma} \|\phi_{\gamma}\|_{L^2(I)} \quad \forall \gamma \in [\gamma_1, \gamma_2],$$

where $C(\gamma_1, \gamma_2) > 0$ is independent of $\gamma$ and $\delta \gamma$. Consequently,

$$\|\delta \phi_{\gamma}\|_{H^1_0(I)} \leq C(\gamma_1, \gamma_2)\sqrt{\delta \gamma} \quad \forall \gamma \in [\gamma_1, \gamma_2].$$

(A.3)

We now calculate $e'(\gamma)$. Denote $\delta e_{\gamma} = e(\gamma + \delta \gamma) - e(\gamma)$ with $\delta \gamma > 0$ as assumed above. By (A.1) with $\eta = \delta \phi_{\gamma}$ for $\phi_{\gamma}$ and (A.1) with $\phi_{\gamma + \delta \gamma}$ replacing $\phi_{\gamma}$, we obtain

$$\frac{\delta e_{\gamma}}{\delta \gamma} = \frac{1}{\delta \gamma} \int_0^1 \left[ \frac{1}{2} \varepsilon_{\gamma + \delta \gamma} \phi_{\gamma + \delta \gamma}^2 - \frac{1}{2} \varepsilon_{\gamma} \phi'_{\gamma}^2 - f \delta \phi_{\gamma} \right] \, dx$$

$$= \frac{1}{2\delta \gamma} \int_0^1 \left[ \varepsilon_{\gamma + \delta \gamma} \phi_{\gamma + \delta \gamma}^2 - \varepsilon_{\gamma} \phi'_{\gamma}^2 - \varepsilon_{\gamma + \delta \gamma} \phi'_{\gamma + \delta \gamma} \phi'_{\gamma + \delta \gamma} - \varepsilon_{\gamma} \phi_{\gamma}(\phi'_{\gamma + \delta \gamma} - \phi'_{\gamma}) \right] \, dx$$

$$= \frac{1}{2\delta \gamma} \int_0^1 (\varepsilon_{\gamma + \delta \gamma} - \varepsilon_{\gamma}) \phi_{\gamma + \delta \gamma} \phi_{\gamma} \, dx$$

$$= \frac{\varepsilon_+ - \varepsilon_-}{2\delta \gamma} \int_\gamma^{\gamma + \delta \gamma} \phi_{\gamma + \delta \gamma} \phi_{\gamma} \, dx.$$
By (A.2) again, we have
\[
\frac{1}{\delta \gamma} \int_{\gamma}^{\gamma + \delta \gamma} \phi'_{\gamma + \delta \gamma}(x) \left[ \phi'_\gamma(x) - \phi'_\gamma(\gamma+) \right] dx + \frac{\phi'_\gamma(\gamma+)}{\delta \gamma} \int_{\gamma}^{\gamma + \delta \gamma} \phi'_{\gamma + \delta \gamma}(x) dx
\]
\[
= \frac{\varepsilon_- - \varepsilon_+}{2} (I_1 + I_2).
\]

It follows from (A.2), the Cauchy–Schwarz inequality, and the bound \( \|\phi_\gamma\|_{H^1(I)} \leq C \) that
\[
|I_1| = \left| \frac{1}{\delta \gamma} \int_{\gamma}^{\gamma + \delta \gamma} \phi'_{\gamma + \delta \gamma}(x) \left( \int_{\gamma}^{x} \phi''_\gamma(y) dy \right) dx \right|
\]
\[
= \left| \frac{1}{\delta \gamma} \int_{\gamma}^{\gamma + \delta \gamma} \phi'_{\gamma + \delta \gamma}(x) \left( \int_{\gamma}^{x} - \frac{1}{\varepsilon_+} f(y) dy \right) dx \right|
\]
\[
\leq C \sqrt{\delta \gamma},
\]
where \( C > 0 \) is a constant independent of \( \gamma \) and \( \delta \gamma \).

We have
\[
I_2 = \frac{\phi'_\gamma(\gamma+) \delta \gamma}{\delta \gamma} \left[ \int_{\gamma}^{\gamma + \delta \gamma} \phi'_{\gamma + \delta \gamma}(x) dx - \int_{\gamma - \delta \gamma}^{\gamma} \phi'_\gamma(x) dx \right] + \frac{\phi'_\gamma(\gamma+) \delta \gamma}{\delta \gamma} \int_{\gamma - \delta \gamma}^{\gamma} \phi'_\gamma(x) dx =: I_{2,1} + I_{2,2}.
\]

Clearly,
\[
I_{2,2} = \frac{\phi'_\gamma(\gamma+) \delta \gamma}{\delta \gamma} \int_{\gamma - \delta \gamma}^{\gamma} \phi'_\gamma(x) dx \rightarrow \phi'_\gamma(\gamma+) \phi'_\gamma(\gamma-) \quad \text{as} \ \delta \gamma \rightarrow 0.
\]

By the change of variable, we get
\[
I_{2,1} = \frac{\phi'_\gamma(\gamma+) \delta \gamma}{\delta \gamma} \int_{\gamma - \delta \gamma}^{\gamma} \left[ \phi'_{\gamma + \delta \gamma}(y + \delta \gamma) - \phi'_\gamma(y) \right] dy
\]
\[
= \frac{\phi'_\gamma(\gamma+) \delta \gamma}{\delta \gamma} \int_{\gamma - \delta \gamma}^{\gamma} \left[ \phi'_{\gamma + \delta \gamma}(y + \delta \gamma) - \phi'_{\gamma + \delta \gamma}(y) \right] dy + \frac{\phi'_\gamma(\gamma+) \delta \gamma}{\delta \gamma} \int_{\gamma - \delta \gamma}^{\gamma} \left[ \phi'_{\gamma + \delta \gamma}(y) - \phi'_\gamma(y) \right] dy
\]
\[
=: I_{2,1,1} + I_{2,1,2}.
\]

It follows from (A.2) that
\[
I_{2,1,1} = \frac{\phi'_\gamma(\gamma+) \delta \gamma}{\delta \gamma} \int_{\gamma - \delta \gamma}^{\gamma} \left[ \phi'_{\gamma + \delta \gamma}(y + \delta \gamma) - \phi'_{\gamma + \delta \gamma}(y) \right] dy
\]
\[
= \frac{\phi'_\gamma(\gamma+) \delta \gamma}{\delta \gamma} \int_{\gamma - \delta \gamma}^{\gamma} \left[ \int_{y}^{y + \delta \gamma} \phi''_{\gamma + \delta \gamma}(x) dx \right] dy
\]
\[
= \frac{\phi'_\gamma(\gamma+)}{\delta \gamma} \int_{\gamma - \delta \gamma}^{\gamma} \left[ - \frac{1}{\varepsilon_-} \int_{y}^{y + \delta \gamma} f(x) dx \right] dy
\]
\[
\rightarrow 0 \quad \text{as} \ \delta \gamma \rightarrow 0.
\]

By (A.2) again, we have
\[
(\delta \phi_\gamma)(y) = \phi''_{\gamma + \delta \gamma}(y) - \phi''_\gamma(y) = -(1/\varepsilon_-) f(y) + (1/\varepsilon_-) f(y) = 0 \quad \forall y \in (\gamma - \delta \gamma, \gamma).
\]
Hence, \((\delta \phi \gamma)') = a \) on \((\gamma - \delta \gamma, \gamma)\) for some constant \(a \in \mathbb{R}\). By (A.3), \(a = 0\). Therefore,

\[
I_{2,1,2} = \frac{\phi'_\gamma(\gamma+)}{\delta \gamma} \int_{\gamma-\delta \gamma}^{\gamma} \left[ \phi'_\gamma(y) - \phi'_\gamma(y) \right] dy \quad \text{and} \quad \int_{\gamma-\delta \gamma}^{\gamma} (\delta \phi \gamma)'(y) dy = 0.
\]

It now follows from (A.4)–(A.10) and the jump condition in (A.2) that

\[
e'(\gamma) = \lim_{\delta \gamma \to 0} \frac{\delta e(\gamma)}{\delta \gamma} = \frac{1}{2}(\varepsilon_+ - \varepsilon_-) \phi'_\gamma(\gamma+)\phi'_\gamma(\gamma-) = \frac{1}{2} \left( \frac{1}{\varepsilon_+} - \frac{1}{\varepsilon_-} \right) [\varepsilon \phi'_\gamma(\gamma)]^2.
\]

\[
\square
\]

Acknowledgment

This work was supported in part by the US National Science Foundation through the grant DMS-2208465. The authors thank Professor Li-Tien Cheng, Dr. Benjamin Ciotti, Professor Shuang Liu, Professor Anthony C. Maggs, Dr. Zirui Zhang, and Professor Shenggao Zhou for helpful discussions. The authors also thank the anonymous referees for their valuable comments and suggestions.
