

### Part I - True/False

1. circle T  F If  $G$  has order  $n$ , it can have a subgroup  $H$  of order  $n-1$  where  $n > 2$ .
2. circle T  F  $G$  is a group. We have  $(ab)^n = a^n b^n$  for all  $a, b \in G$  and  $n > 0$ .
3. circle T  F If  $x^2 = e$  for all  $x$  in  $G$  then  $G$  is abelian.
4. circle T  F If  $H_1$  and  $H_2$  are subgroups of the same order in an abelian group  $G$  then  $H_1 = H_2$ .
5. circle T  F If  $H$  is a normal subgroup of  $G$  and if  $H$  and  $G/H$  are abelian, then  $G$  is abelian.
6. circle T  F A normal subgroup is always abelian
7. circle T  F A subgroup which is abelian is always normal
8. circle T  F If  $G$  is abelian then every subgroup of  $G$  is normal
9. circle T  F A subgroup of prime order is always normal
10. circle T  F A subgroup of prime index is always normal

Part II - longer problems

1. Let  $G$  be a group and  $H$  a subgroup. Prove the following statements about right cosets:

- a.  $H$  is a right coset of  $H$
- b. Any element of  $G$  is in some right coset of  $H$ .
- c. The right cosets are disjoint in the sense that  $\forall a, b \in G$  either  $Ha = Hb$  or  $Ha \cap Hb = \emptyset$  (empty set)
  - a.  $H = He$ , the right coset of the identity element
  - b.  $a = ea \in Ha$
  - c. If  $c \in Ha \cap Hb$  we have  $c = ha = kb$  for  $h, k \in H$  so  $a = h^{-1}kb \in Hb$  and therefore  $Ha \subset Hb$ . Similarly  $Hb \subset Ha$  so  $Ha = Hb$ .

2. a. Find all subgroups of  $S_3$  and construct the subgroup lattice.  
 b. Find all subgroups of  $Z_6$  and construct the subgroup lattice.

3.  $H$  is a subgroup of a group  $G$ . Show that if  $|H| = \frac{1}{2} |G|$  then  $H$  is normal

A subgroup is normal if and only if every right coset is a left coset. In this case there are only two cosets (left or right) one of which is  $H = eH = He$ . If  $a$  is not in  $H$  then  $aH = Ha$  consists of the elements of  $G$  which are not in  $H$ . So every left coset is a right coset.

4. Let  $G$  be a group and  $a \in G$ . The centralizer of  $a$  is the set  $C(a) = \{x \in G \mid xa = ax\}$
- Show that  $C(a)$  is a subgroup of  $G$
  - Compute  $C(a)$  if  $G = S_3$  and  $a = (1,2,3)$
  - Compute  $C(a)$  if  $G = S_3$  and  $a = (1,2)$

a. If  $x, y \in C(a)$  then  $xya = x(ay) = (xa)y = axy$  -- so  $C(a)$  is closed

multiply  $ax = xa$  on the left and right by  $x^{-1}$  to obtain  $x^{-1}a = ax^{-1}$  so  $C(a)$  is closed under inverse

b. We will use Lagrange's theorem.  $|C(a)|$  divides 6, which is the order of the group. Note that  $e, a = (1\ 2\ 3), a^2 = (1\ 3\ 2)$  all commute with  $a$ . So  $C(a)$  has at least 3 elements. However  $(1\ 2)$  does not commute with  $(1\ 2\ 3)$ . So  $C(a)$  cannot be of order 6 -- so  $C(a) = \langle (1\ 2\ 3) \rangle$

c. The same argument applies when  $a = (1\ 2)$ . The subgroup  $C(a)$  contains  $\langle (1\ 2) \rangle$  but cannot be of order 6 since  $(1\ 2\ 3)$  does not commute with  $(1\ 2)$
